Functional Description

The CY7C188 is a high-performance CMOS static RAM organized as 32,768 words by 9 bits. Easy memory expansion is provided by an active-LOW chip enable ($\overline{CE}_1$), an active-HIGH chip enable (CE_2), an active-LOW output enable ($\overline{OE}$), and tri-state drivers. The device has an automatic power-down feature that reduces power consumption by more than 75% when deselected.

Writing to the device is accomplished by taking $\overline{CE}_1$ and write enable ($\overline{WE}$) inputs LOW and CE_2 input HIGH. Data on the nine I/O pins (I/O_0 – I/O_8) is then written into the location specified on the address pins (A_0 – A_{14}).

Reading from the device is accomplished by taking $\overline{CE}_1$ and $\overline{OE}$ LOW while forcing $\overline{WE}$ and CE_2 HIGH. Under these conditions, the contents of the memory location specified by the address pins will appear on the I/O pins.

The nine input/output pins (I/O_0 – I/O_8) are placed in a high-impedance state when the device is deselected ($\overline{CE}_1$ HIGH or CE_2 LOW), the outputs are disabled ($\overline{OE}$ HIGH), or during a write operation ($\overline{CE}_1$ LOW, CE_2 HIGH, and $\overline{WE}$ LOW).

The CY7C188 is available in standard 300-mil-wide SOJ.

Notes

4. Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V, and output loading of the specified I_{OL}/I_{OH} and 30-pF load capacitance.
5. t_{HZOE}, t_{HZCE}, and t_{HZWE} are specified with C_L = 5 pF as in part (b) of AC Test Loads. Transition is measured ±500 mV from steady-state voltage.
6. See the last page of this specification for Group A subgroup testing information.
7. At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any given device.
8. The internal write time of the memory is defined by the overlap of $\overline{CE}_1$, LOW, CE_2 HIGH, and $\overline{WE}$ LOW. All three signals must be asserted to initiate a write and any signal can terminate a write by being deasserted. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
9. The minimum write cycle time for write cycle #3 ($\overline{WE}$ controlled, $\overline{OE}$ LOW) is the sum of t_{HZWE} and t_{SD}.

Notes

10. Device is continuously selected. $\overline{OE}$, $\overline{CE}$ = V_{IL}.
11. $\overline{WE}$ is HIGH for read cycle.
12. Address valid prior to or coincident with $\overline{CE}$ transition LOW.
13. Timing parameters are the same for all chip enable signals ($\overline{CE_1}$ and CE_2), so only the timing for $\overline{CE_1}$ is shown.
14. The internal write time of the memory is defined by the overlap of $\overline{CE_1}$, LOW, CE_2 HIGH, and $\overline{WE}$ LOW. All three signals must be asserted to initiate a write and any signal can terminate a write by being deasserted. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
15. Data I/O is high impedance if $\overline{OE}$ = V_{IH}.
16. If $\overline{CE}$ goes HIGH simultaneously with $\overline{WE}$ HIGH, the output remains in a high-impedance state.
17. During this period, the I/Os are in the output state and input signals should not be applied.
