

### DESCRIPTION

The MP18021A is a high-frequency, 100V, half bridge, N-channel power MOSFET driver. Its low side and high side driver channels are independently controlled and matched with a time delay of less than 5ns. Under-voltage lockout on both high side and low side supplies force their outputs low in case of insufficient supply. The integrated bootstrap diode reduces external component count.

### FEATURES

- Drives N-Channel MOSFET Half Bridge
- 100V  $V_{BST}$  Voltage Range
- On-Chip Bootstrap Diode
- Typical 16ns Propagation Delay Time
- Less Than 5ns Gate Drive Matching
- Drives 1nF Load with 12ns/9ns Rise/Fall Times with 12V VDD
- TTL Compatible Input
- Less Than 150 $\mu$ A Quiescent Current
- UVLO for Both High Side and Low Side
- In SOIC8E and QFN8 (3 $\times$ 3mm) Packages

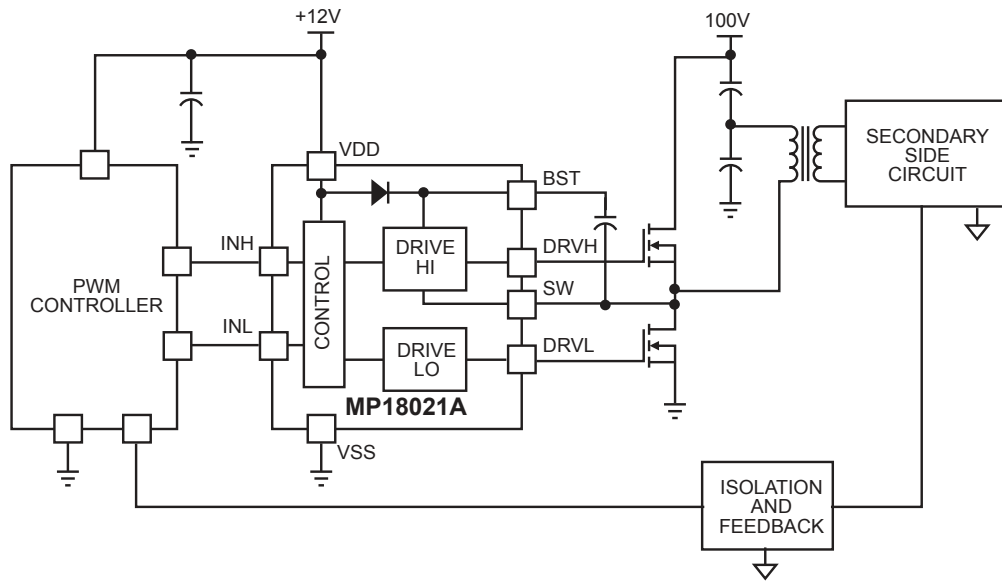

### APPLICATIONS

- Telecom Half Bridge Power Supplies
- Avionics DC-DC Converters
- Two-Switch Forward Converters
- Active Clamp Forward Converters

#### Thermal Resistance <sup>(4)</sup>

	$\theta_{JA}$	$\theta_{JC}$
SOIC8E	48	10... °C/W
QFN8 (3x3mm)	50	12... °C/W

#### Notes:

- Exceeding these ratings may damage the device.
- The maximum allowable power dissipation is a function of the maximum junction temperature  $T_{J(MAX)}$ , the junction-to-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature  $T_A$ . The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$ . Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- The device is not guaranteed to function outside of its operating conditions.
- Measured on JESD51-7, 4-layer PCB.

## PIN FUNCTIONS

Pin #	Name	Description
1	VDD	Supply input. This pin supplies power to all the internal circuitry. A decoupling capacitor to ground must be placed close to this pin to ensure stable and clean supply.
2	BST	Bootstrap. This is the positive power supply for the internal floating high-side MOSFET driver. Connect a bypass capacitor between this pin and SW pin.
3	DRVH	Floating driver output.
4	SW	Switching node.
5	INH	Control signal input for the floating driver.
6	INL	Control signal input for the low side driver.
7	VSS, Exposed Pad	Chip ground. Connect exposed pad to VSS for proper thermal operation.
8	DRVL	Low side driver output.

### APPLICATION

The input signals of INH and INL can be controlled independently. If both INH and INL are controlling HSFET and LSFET of the same bridge, then users must avoid shoot through by

setting sufficient dead time between INH and INL low, and vice versa. See below figure. Dead time is defined as the time interval between INH low and INL low.

## REFERENCE DESIGN CIRCUITS

### Half Bridge Converter

In half-bridge converter topology, the MOSFETs are driven alternately with some dead time. Therefore, INH and INL are driven with

alternating signals from the PWM controller. The input voltage can be up to 100V in this application.

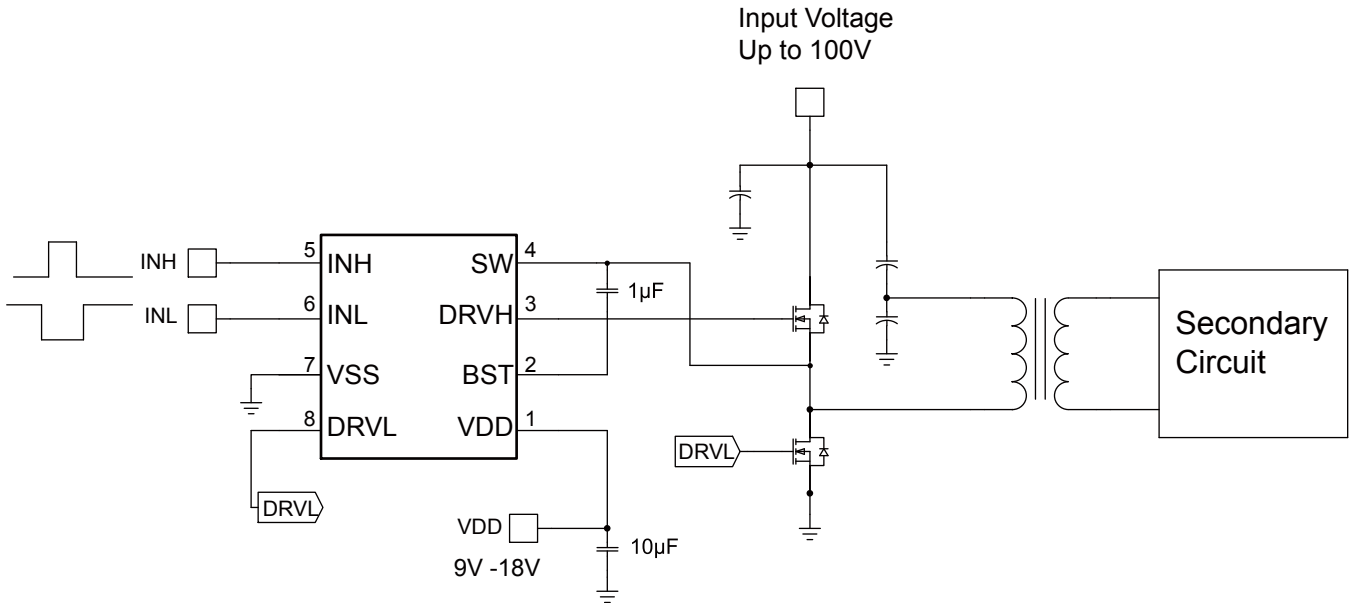

Figure 3 – Half Bridge Converter

### Two-Switch Forward Converter

In two-switch forward converter topology, both MOSFETs are turned on and off together. The input signal (INH and INL) comes from the PWM controller, which senses the output voltage (and output current if current-mode control is used).

The Schottky diodes clamp the reverse swing of the power transformer and must be rated at the input voltage. The input voltage can be up to 100V in this circuit.

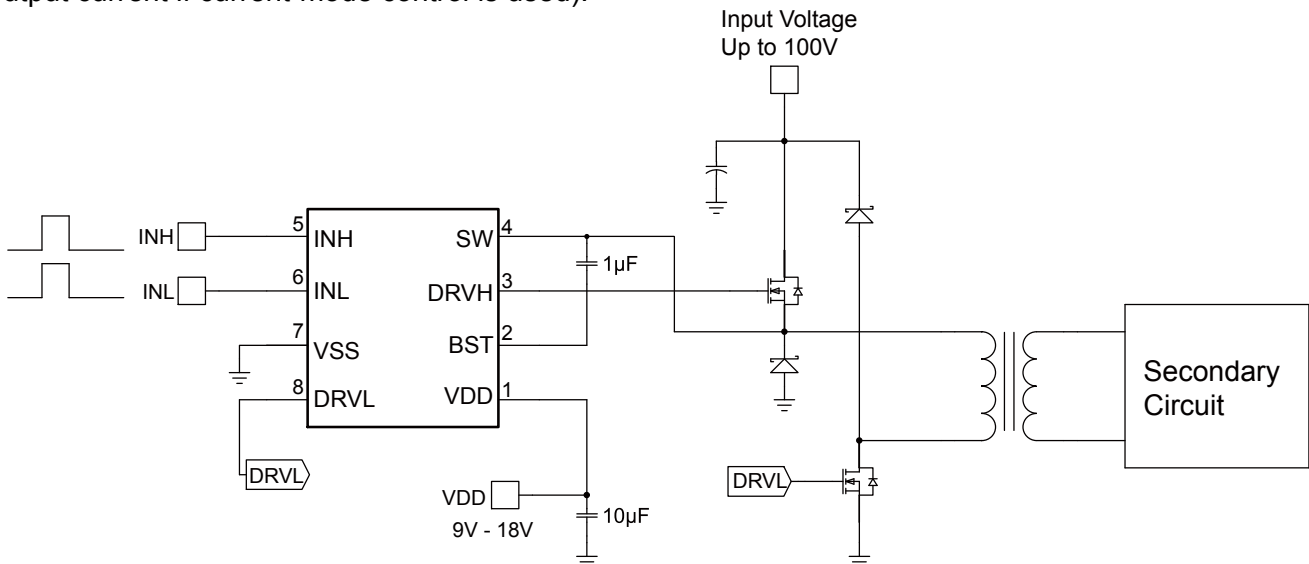

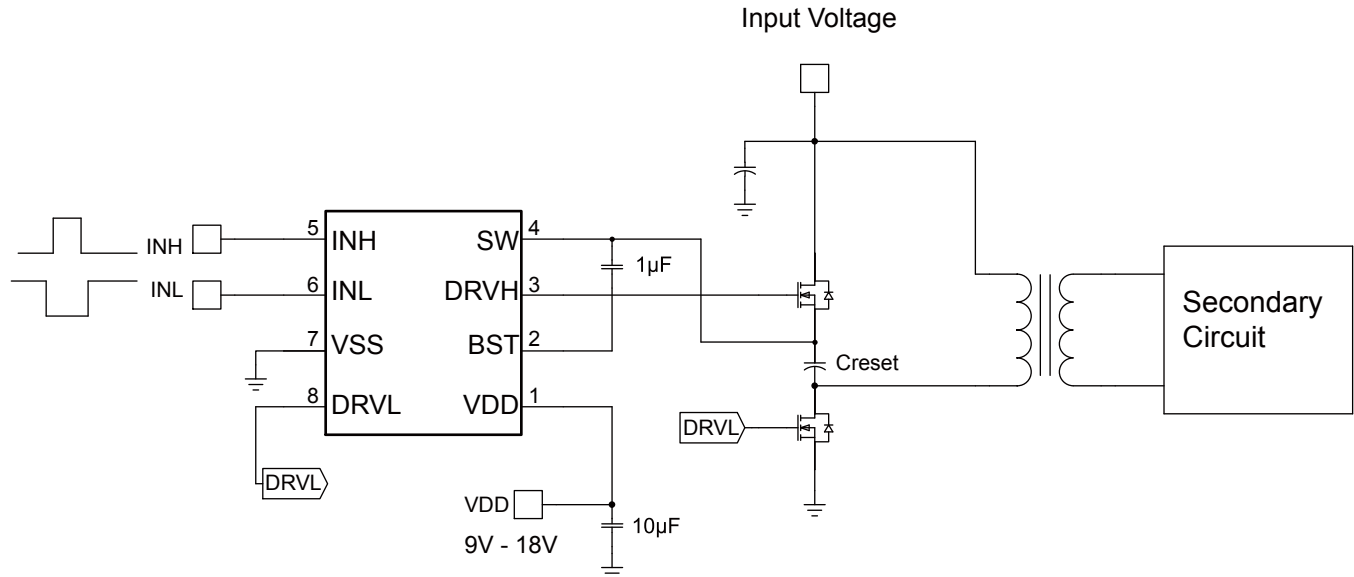

Figure 4 – Two-Switch Forward Converter

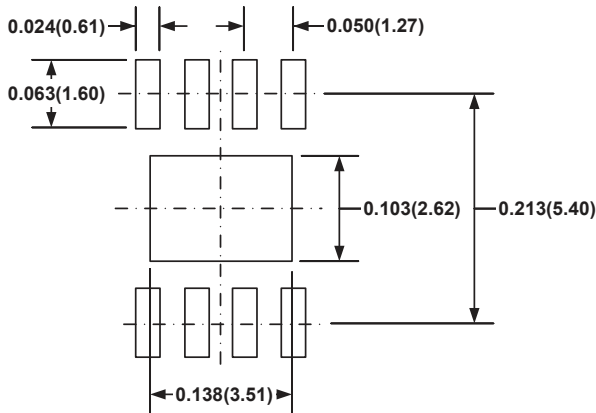

### Active-Clamp Forward Converter

In active-clamp forward converter topology, the MOSFETs are driven alternately. The high-side MOSFET, along with capacitor  $C_{reset}$ , is used to reset the power transformer in a lossless manner.

This topology lends itself well to run at duty cycles exceeding 50%. For these reasons, the input voltage may not be able to run at 100V for this application.
