

### Differential Line Receiver

The EL2142 is a very high bandwidth amplifier designed to extract the difference signal from noisy environments, and is thus primarily targeted for applications such as receiving signals from twisted pair lines, or any application where common mode noise injection is likely to occur.

The EL2142 is stable for a gain of one, and requires two external resistors to set the voltage gain.

The output common mode level is set by the reference pin ( $V_{REF}$ ), which has a -3dB bandwidth of over 100MHz. Generally, this pin is grounded, but it can be tied to any voltage reference.

The output can deliver a minimum of  $\pm 50\text{mA}$  and is short circuit protected to withstand a temporary overload condition.

NOTE: Intersil Pb-free products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

### Features

- Differential input range  $\pm 2.3\text{V}$
- 150MHz 3dB bandwidth
- 400V/ $\mu\text{s}$  slewrate
- $\pm 5\text{V}$  supplies or single supply
- 50mA minimum output current
- Output swing (100 $\Omega$  load) to within 1.5V of supplies
- Low power-11mA typical supply current
- Pb-free available (RoHS compliant)

### Applications

- Twisted pair receiver
- Differential line receiver
- VGA over twisted pair
- ADSL/HDSL receiver
- Differential to single ended amplification.
- Reception of analog signals in a noisy environment.

**Typical Performance Curves**

**Applications Information**

**Gain Equation**

$V_{OUT} = ((R2+R1)/R1) \times (V_{IN}-V_{INB}+V_{REF})$  when R1 tied to GND

$V_{OUT} = ((R2+R1)/R1) \times (V_{IN}-V_{INB})$  when R1 tied to  $V_{REF}$

**Choice of Feedback Resistor**

For a gain of one,  $V_{OUT}$  may be shorted back to  $V_{FB}$ , but 100Ω-200Ω improves the bandwidth. For gains greater than

one, there is little to be gained from choosing resistor R1 value below 200Ω, for it would only result in increased power dissipation and potential signal distortion. Above 200Ω, the bandwidth response will develop some peaking (for a gain of one), but substantially higher R1 values may be used for higher voltage gains, such as up to 1kΩ at a gain of four before peaking will develop.

**Capacitance Considerations**

As with many high bandwidth amplifiers, the EL2142 prefers not to drive highly capacitive loads. It is best if the capacitance on  $V_{OUT}$  is kept below 10pF if the user does not want gain peaking to develop. The  $V_{FB}$  node forms a potential pole in the feedback loop, so capacitance should be minimized on this node for maximum bandwidth.

The amount of capacitance tolerated on any of these nodes in an actual application will also be dependent on the gain setting and the resistor values in the feedback network.
