RESET_IN# - Assertion (transition from '1' to '0')

Asserting RESET_IN pin stops all the outputs including CPU, SRC, ATIG, PCI and USB with the REF[2:0] running. The pin is a Schmitt trigger input with debouncing. After it is triggered, REF clocks will wait for two clock cycle to ensure the RESET_IN is asserted. Then, it will take 3 μ s for the clocks to stop without glitches. The clock chip will be power down and re-power up, and SMBus will be reloaded. It will take no more than 2.5mS for the clocks to come out with correct frequencies and no glitches.

**** Deassertion of RESET_IN# (transition from '0' to '1') has NO effect on the clocks.**

Shared Pin Operation - Input/Output Pins

The I/O pins designated by (input/output) on the **ICS951462** serve as dual signal functions to the device. During initial power-up, they act as input pins. The logic level (voltage) that is present on these pins at this time is read and stored into a 5-bit internal data latch. At the end of Power-On reset, (see AC characteristics for timing values), the device changes the mode of operations for these pins to an output function. In this mode the pins produce the specified buffered clocks to external loads.

To program (load) the internal configuration register for these pins, a resistor is connected to either the VDD (logic 1) power supply or the GND (logic 0) voltage potential. A 10 Kiloohm (10K) resistor is used to provide both the solid CMOS programming voltage needed during the power-up programming period and to provide an insignificant load on the output clock during the subsequent operating period. Figure 1 shows a means of implementing this function when a switch or 2 pin header is used. With no jumper is installed

the pin will be pulled high. With the jumper in place the pin will be pulled low. If programmability is not necessary, than only a single resistor is necessary. The programming resistors should be located close to the series termination resistor to minimize the current loop area. It is more important to locate the series termination resistor close to the driver than the programming resistor.
