## 3 Parameter Classification

The electrical parameters shown in this supplement are guaranteed by various methods. To give the customer a better understanding, the following classification is used and the parameters are tagged accordingly in the tables where appropriate:

**Table 1. Parameter Classifications**

P	Those parameters are guaranteed during production testing on each individual device.
C	Those parameters are achieved by the design characterization by measuring a statistically relevant sample size across process variations.
T	Those parameters are achieved by design characterization on a small sample size from typical devices under typical conditions unless otherwise noted. All values shown in the typical column are within this category.
D	Those parameters are derived mainly from simulations.

### NOTE

The classification is shown in the column labeled “C” in the parameter tables where appropriate.

## 4.4 Voltage and current operating ratings

Absolute maximum ratings are stress ratings only, and functional operation at the maxima is not guaranteed. Stress beyond the limits specified in below table may affect device reliability or cause permanent damage to the device. For functional operating conditions, refer to the remaining tables in this document.

This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (for instance, either V<sub>SS</sub> or V<sub>DD</sub>) or the programmable pullup resistor associated with the pin is enabled.

Symbol	Description	Min.	Max.	Unit
V <sub>DD</sub>	Supply voltage	-0.3	5.8	V
I <sub>DD</sub>	Maximum current into V <sub>DD</sub>	—	120	mA

1. Typical values are measured at 25 °C. Characterized, not tested.
2. Only PTB4, PTB5 support ultra high current output.
3. The specified resistor value is the actual value internal to the device. The pullup value may appear higher when measured externally on the pin.
4. All functional non-supply pins, except for PTA2 and PTA3, are internally clamped to V<sub>SS</sub> and V<sub>DD</sub>.
5. Input must be current-limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values for positive and negative clamp voltages, then use the large one.
6. Power supply must maintain regulation within operating V<sub>DD</sub> range during instantaneous and operating maximum current conditions. If the positive injection current (V<sub>in</sub> > V<sub>DD</sub>) is higher than I<sub>DD</sub>, the injection current may flow out of V<sub>DD</sub> and could result in external power supply going out of regulation. Ensure that external V<sub>DD</sub> load will shunt current higher than maximum injection current when the MCU is not consuming power, such as no system clock is present, or clock rate is very low (which would reduce overall power consumption).

### 5.1.3 EMC performance

Electromagnetic compatibility (EMC) performance is highly dependant on the environment in which the MCU resides. Board design and layout, circuit topology choices, location and characteristics of external components as well as MCU software operation all play a significant role in EMC performance. The system designer should consult Freescale applications notes such as AN2321, AN1050, AN1263, AN2764, and AN1259 for advice and guidance specifically targeted at optimizing EMC performance.

## 5.3 Thermal specifications

### 5.3.1 Thermal characteristics

This section provides information about operating temperature range, power dissipation, and package thermal resistance. Power dissipation on I/O pins is usually small compared to the power dissipation in on-chip logic and voltage regulator circuits, and it is user-determined rather than being controlled by the MCU design. To take  $P_{I/O}$  into account in power calculations, determine the difference between actual pin voltage and  $V_{SS}$  or  $V_{DD}$  and multiply by the pin current for each I/O pin. Except in cases of unusually high pin current (heavy loads), the difference between pin voltage and  $V_{SS}$  or  $V_{DD}$  will be very small.

**Table 8. Thermal characteristics**

Rating	Symbol	Value	Unit
Operating temperature range (packaged)	$T_A$	$T_L$ to $T_H$ -40 to 125	$^{\circ}\text{C}$
Junction temperature range	$T_J$	-40 to 135	$^{\circ}\text{C}$
Thermal resistance single-layer board			
64-pin LQFP	$\theta_{JA}$	71	$^{\circ}\text{C}/\text{W}$
48-pin LQFP	$\theta_{JA}$	81	$^{\circ}\text{C}/\text{W}$
32-pin LQFP	$\theta_{JA}$	86	$^{\circ}\text{C}/\text{W}$
Thermal resistance four-layer board			
64-pin LQFP	$\theta_{JA}$	53	$^{\circ}\text{C}/\text{W}$
48-pin LQFP	$\theta_{JA}$	57	$^{\circ}\text{C}/\text{W}$
32-pin LQFP	$\theta_{JA}$	57	$^{\circ}\text{C}/\text{W}$

The average chip-junction temperature ( $T_J$ ) in  $^{\circ}\text{C}$  can be obtained from:

$$T_J = T_A + (P_D \times \theta_{JA})$$

Where:

$T_A$  = Ambient temperature,  $^{\circ}\text{C}$

$\theta_{JA}$  = Package thermal resistance, junction-to-ambient,  $^{\circ}\text{C}/\text{W}$

$$P_D = P_{\text{int}} + P_{\text{I/O}}$$

$P_{\text{int}}$  =  $I_{\text{DD}} \times V_{\text{DD}}$ , Watts - chip internal power

$P_{\text{I/O}}$  = Power dissipation on input and output pins - user determined

For most applications,  $P_{\text{I/O}} \ll P_{\text{int}}$  and can be neglected. An approximate relationship between  $P_D$  and  $T_J$  (if  $P_{\text{I/O}}$  is neglected) is:

$$P_D = K \div (T_J + 273 \text{ }^{\circ}\text{C})$$

Solving the equations above for  $K$  gives:

$$K = P_D \times (T_A + 273 \text{ }^{\circ}\text{C}) + \theta_{JA} \times (P_D)^2$$

where  $K$  is a constant pertaining to the particular part.  $K$  can be determined by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of  $K$ , the values of  $P_D$  and  $T_J$  can be obtained by solving the above equations iteratively for any value of  $T_A$ .

1. Data in Typical column was characterized at 5.0 V, 25 °C or is typical recommended value.
2. When ICS is configured for FEE or FBE mode, input clock source must be divisible using RDIV to within the range of 31.25 kHz to 39.0625 kHz.
3. See crystal or resonator manufacturer's recommendation.
4. Load capacitors ( $C_1, C_2$ ), feedback resistor ( $R_F$ ) and series resistor ( $R_S$ ) are incorporated internally when RANGE = HGO = 0.
5. This parameter is characterized and not tested on each device.
6. Proper PC board layout procedures must be followed to achieve specifications.
7. This specification applies to any time the FLL reference source or reference divider is changed, trim value changed, DMX32 bit is changed, DRS bit is changed, or changing from FLL disabled (FBELP, FBILP) to FLL enabled (FEI, FEE, FBE, FBI). If a crystal/resonator is being used as the reference, this specification assumes it is already running.
8. Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum  $f_{\text{Bus}}$ . Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the FLL circuitry via  $V_{\text{DD}}$  and  $V_{\text{SS}}$  and variation in crystal oscillator frequency increase the  $C_{\text{Jitter}}$  percentage for a given interval.

## 6.4 Communication interfaces

### 6.4.1 SPI switching specifications

The serial peripheral interface (SPI) provides a synchronous serial bus with master and slave operations. Many of the transfer attributes are programmable. The following tables provide timing characteristics for classic SPI timing modes. Refer to the SPI chapter of the chip's reference manual for information about the modified transfer formats used for communicating with slower peripheral devices. All timing is shown with respect to 20%  $V_{DD}$  and 70%  $V_{DD}$ , unless noted, and 100 pF load on all SPI pins. All timing assumes slew rate control is disabled and high drive strength is enabled for SPI output pins.

1. This is a high current drive pin when operated as output.
2. This is a true open-drain pin when operated as output.

**Note**

When an alternative function is first enabled, it is possible to get a spurious edge to the module. User software must clear any associated flags before interrupts are enabled. The table above illustrates the priority if multiple modules are enabled. The highest priority module will have control over the pin. Selecting a higher priority pin function with a lower priority function already enabled can cause spurious edges to the lower priority module. Disable all modules that share a pin before enabling another module.

## 8.2 Device pin assignment

Pins in **bold** are not available on less pin-count packages.
