

ISL8560

DC/DC Power Switching Regulator

FN9244

Rev 7.00

September 19, 2008

The ISL8560 is a step down DC/DC power switching regulator which accepts 9.0V to 60V input and provides a 2A output current. The output voltage can be set in the range between 1.21V and 55V by means of an external divider. The device uses an internal power DMOS transistor with a typical  $r_{DS(ON)}$  of 0.19Ω to obtain very high efficiency and high switching speed. A switching frequency in the range of 100kHz to 600kHz can be realized (the maximum power dissipation of the various packages must be observed). Notable features of this next generation of DC/DC converter includes pulse-by-pulse current limit for FET protection, hiccup mode for short circuit protection, voltage feedforward regulation, Frequency SYNC, soft-start, low standby current of 60μA typical in the disabled state, and thermal shut-down. The device is available in a 20 Ld QFN package.

**Ordering Information**

PART NUMBER (Note)	PART MARKING	TEMP. RANGE (°C)	PACKAGE (Pb-Free)	PKG. DWG. #
ISL8560IRZ	ISL 8560IRZ	-40 to +85	20 Ld 6x6 QFN	L20.6x6B
ISL8560IRZ-T*	ISL 8560IRZ	-40 to +85	20 Ld 6x6 QFN	L20.6x6B

\*Please refer to TB347 for details on reel specifications.

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

**Features**

- Voltage feedforward mode
- Step down DC/DC supporting up to 2A
- Input voltage range of 9.0V to 60V
- Internal reference of 1.21V ±1%
- Adjustable output voltage range of 1.21V to 55V
- Adjustable switching frequency 100kHz to 600kHz
- Frequency SYNC pin
- Zero load current operation
- Pulse-by-pulse mode current limit and Hiccup mode
- Low standby current of 60μA typical
- Thermal shut-down
- Load dump to 100V for 400ms
- Pb-Free (RoHS compliant)

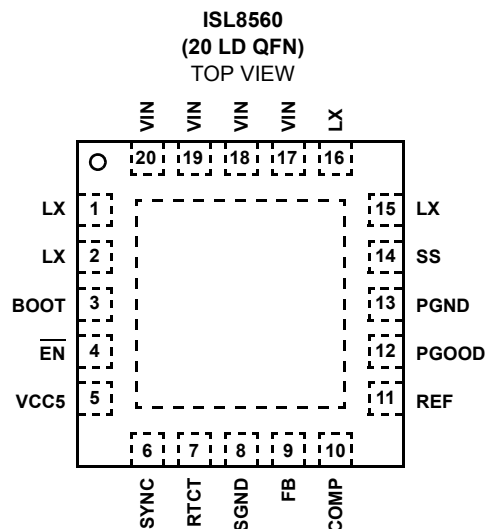

**Applications**

- Industrial and automotive power supplies
- Portable computers
- Battery chargers
- Distributed power systems

**Related Literature**

- Technical Brief TB363 “Guidelines for Handling and Processing Moisture Sensitive Surface Mount Devices (SMDs)”

**Pinout**

**Absolute Maximum Ratings**

Input Voltage VIN	GND - 0.3V to 72V
Voltage at BOOT pin	GND - 0.3V to 82V
LX, RTCT	GND - 0.3V to 60V
REF, FB, SS, EN, SYNC, PGOOD pins	.8V
VCC5*	GND - 0.3V to 5.5V

**Recommended Operating Conditions**

Junction Temperature Range	-40°C to +125°C
Supply Voltage Range (Typical)	9.0V to 60V

**CAUTION:** Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

\*An accidental short between VCC5 and GND may cause excessive heating and permanent damage to the device.

**NOTES:**

1.  $\theta_{JA}$  is measured in free air with the component mounted on a high effective thermal conductivity test board with "direct attach" features. See Tech Brief TB379.
2. For  $\theta_{JC}$ , the "case temp" location is the center of the exposed metal pad on the package underside.
3. Additional heatsinking may be required to insure that the junction temperature does not exceed above +125°C.

**Thermal Information**

Thermal Resistance (Typical, Notes 1, 2)	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)
QFN Package	30	1.5
Maximum Power Dissipation	3W	
Maximum Junction Temperature (Hermetic Package or Die)	+150°C	
Maximum Junction Temperature (Plastic Package)	+150°C	
Maximum Storage Temperature Range	-65°C to +150°C

## Pin Descriptions

### LX (Pins 1, 2, 15, 16)

There are four output pins that must be connected together externally in normal operation.

### BOOT (Pin 3)

A capacitor is connected from this pin to the output pin. An internal 10V supply and an internal Schottky diode provide the high side voltage to drive the gate of the output DMOS device.

### $\overline{EN}$ (Pin 4)

The  $\overline{EN}$  input will disable the part and shut-down all function when it is held high or left OPEN. The  $\overline{EN}$  current will be 10 $\mu$ A typical. An internal pull-up resistor will hold the pin high. When  $\overline{EN}$  = Low, the part is enabled. Connect to GND for auto start-up.

### VCC5 (Pin 5)

VCC5 is the +5.0V output pin which provides an output of an internal supply for supply filtering purposes. A 1 $\mu$ F capacitor should be connected from this pin to GND. Internal VDD supply is set at 5.0V (not planned that the user would use this supply).

### SYNC (Pin 6)

This pin provides a digital input pin to synchronize the internal oscillator to an external signal. When the sync function is not used, this pin can be left open or tied to GND. If the sync function is used, the RTCT timing must be set to a frequency lower than the sync input frequency. The termination of the ramp is synchronized with the rising edge of the sync input signal. There are no duty cycle restrictions on the input sync signal. Input thresholds are TTL compatible.

### RTCT (Pin 7)

A resistor to VIN and a capacitor to GND determine the frequency of the saw-tooth oscillator. Resistor range is R = 20k to 100k. Capacitor range is C = 470pF to 1.2nF. The oscillator amplitude will vary from approximately 0.9V to 10V as  $V_{IN}$  changes from 8.5V to 60V to maintain constant frequency and provide feed forward. The oscillator will have a fixed off time, which will establish the maximum on time for the regulator. This off time will be <200ns. The maximum duty cycle for a 500kHz system will therefore be approximately 90% as the frequency of the maximum duty cycle will increase (95% for 250kHz system). The minimum duty cycle is zero.

### SGND (Pin 8)

The SGND terminal of the ISL8560 provides the return path for the control and monitor portions of the IC.

### FB (Pin 9)

This is the feedback pin. The feedback ratio is set by an external resistor divider connected to the load.

### COMP (Pin 10)

This pin is connected to the output of the Error Amplifier and is used to compensate the loop. The Error Amplifier is a GM amplifier.

### REF (Pin 11)

1.20V reference output. Bypass to GND with 0.01 $\mu$ F capacitor.

### PGOOD (Pin 12)

This pin is an open drain output that is turned on when the feedback voltage is more than  $\pm 10\%$  from the reference voltage, indicating that the output is not within 10% of set point.

### PGND (Pin 13)

This pin is used as the ground connection of the power train.

### SS (Pin 14)

A capacitor is connected from this pin to GND to determine the soft-start timing. The soft-start pin internal charging current is 10 $\mu$ A.

### VIN (Pins 17, 18, 19, 20)

The input supply for the PWM regulator power stage. Connected to DRAIN of the high side MOSFET.

## Applications Information

### Product Description

The ISL8560 is a non-synchronous, integrated FET 2A step down regulator which operates from an unregulated input of 9V to 60V. The output voltage is user-adjustable with a pair of external resistors. Frequency of operation is adjustable from 100kHz to 600kHz set by RTCT. An external signal with higher frequency can be injected to SYNCH to synchronize the controller.

The buck controller drives an internal N-Channel MOSFET and requires an external diode to deliver load current up to 2A. A Schottky diode is recommended for improved efficiency and performance over a standard diode. The converter output is regulated down to 1.21V from an input source.

The PWM control loop uses a single output voltage loop with input voltage feed forward which simplifies feedback loop compensation and rejects input voltage variation. External feedback loop compensation allows flexibility in output filter component selection.

The buck regulator is equipped with a lossless current limit scheme. The current limit in the buck regulator is achieved by monitoring the drain-to-source current of the internal switching power MOSFET. The current limit threshold is internally set at 4.5A peak. Additional features include programmable soft-start to support proper start-up of wide output capacitance range.

### Start-Up and Shut-Down

When the  $\overline{\text{EN}}$  pin is connected to a logic high, the ISL8560 is in the shut-down mode. All the control circuitry and both MOSFETs are off, and  $V_{\text{OUT}}$  falls to zero. In this mode, the total input current is less than 110 $\mu\text{A}$ .

When the  $\overline{\text{EN}}$  pin is tied to GND, and  $V_{\text{IN}}$  reaches approximately 9V, the regulator begins to switch. The output voltage is gradually increased to ensure proper soft-start operation.

When the  $\overline{\text{EN}}$  reaches logic LOW, the regulator repeats the start-up procedure, including the soft-start function. Connect a capacitor from SS pin to ground. This capacitor, along with an internal 10 $\mu\text{A}$  current source sets the soft-start interval of the converter,  $t_{\text{SS}}$ .

$$C_{\text{SS}}[\mu\text{F}] \approx 8.3 \cdot t_{\text{SS}}[\text{s}] \quad (\text{EQ. 1})$$

### Operating Frequency

The ISL8560 can operate at switching frequencies from 100kHz to 600kHz. A resistor tied from the RTCT pin to  $V_{\text{IN}}$  and a capacitor from RTCT to GND are used to program the switching frequency through Equation 2.

$$C_1[\text{nF}] = \frac{6.25}{R[\text{k}\Omega]} \left( \frac{1000}{f_{\text{OSC}}[\text{kHz}]} - 0.3 \right) \quad (\text{EQ. 2})$$

Caution: When the ISL8560 is in disabled state, the voltage across RTCT pin will reach  $V_{\text{IN}}$  voltage. Make sure that the voltage rating of the RTCT capacitor is rated as high as the input voltage.

### Output Voltage Selection

The output voltage of the regulator can be programmed via an external resistor divider that is used to scale the output voltage relative to the internal reference voltage and feed it back to the inverting input of the error amplifier. Refer to Figure 30.

The output voltage programming resistor,  $R_3$ , will depend on the value chosen for the feedback resistor and the desired output voltage of the regulator. The value for the feedback resistor is typically between 1k $\Omega$  and 10k $\Omega$ .

$$R_3 = \frac{R_2 \times 1.21\text{V}}{V_{\text{OUT}} - 1.21\text{V}} \quad (\text{EQ. 3})$$

If the output voltage desired is 1.21V, then  $R_3$  is left unpopulated.

### Fault Protection

The ISL8560 monitors the output of the regulator for overcurrent and undervoltage events. The ISL8560 also provides protection from excessive junction temperatures.

### Overcurrent Protection

The overcurrent function protects the switching converter from a shorted output by monitoring the current flowing through the upper MOSFETs.

Upon detection of overcurrent condition, the upper MOSFET will be immediately turned off and will not be turned on again until the next switching cycle. Upon detection of the initial overcurrent condition, the overcurrent fault counter is set to 1 and the overcurrent condition flag is set from LOW to HIGH. If, on the subsequent cycle, another overcurrent condition is detected, the OC fault counter will be incremented. If there are seven sequential OC fault detections, the regulator will be shut down under an overcurrent fault condition. An overcurrent fault condition will result with the regulator attempting to restart in a hiccup mode with the delay between restarts being 4 soft-start periods. At the end of the fourth soft-start wait period, the fault counters are reset and soft-start is attempted again. If the overcurrent condition goes away prior to the OC fault counter reaching a count of four, the overcurrent condition flag will set back to LOW.

If the overcurrent condition flag is HIGH and the overcurrent fault counter is less than four and an undervoltage event is detected, the regulator will be shut down immediately.

### Undervoltage Protection

If the voltage detected on the FB pin falls 14% below the internal reference voltage and the overcurrent condition flag is LOW, then the regulator will be shut down immediately under an undervoltage fault condition. An undervoltage fault condition will result with the regulator attempting to restart in a hiccup mode with the delay between restarts being 4 soft-start periods. At the end of the fourth soft-start wait period, the fault counters are reset and soft-start is attempted again.

### Thermal Protection

If the ISL8560 IC junction temperature reaches a nominal temperature of +150°C, the regulator will be disabled. The ISL8560 will not re-enable the regulator until the junction temperature drops below +135°C.

### Output Capacitor Selection

An output capacitor is required to filter the inductor current and supply the load transient current. The filtering requirements are a function of the switching frequency and the ripple current. The load transient requirements are a function of the slew rate ( $di/dt$ ) and the magnitude of the transient load current. These requirements are generally met with a mix of capacitors and careful layout.

High frequency capacitors initially supply the transient and slow the current load rate seen by the bulk capacitors. The bulk filter

capacitor values are generally determined by the ESR (Effective Series Resistance) and voltage rating requirements rather than actual capacitance requirements.

High frequency decoupling capacitors should be placed as close to the power pins of the load as physically possible. Be careful not to add inductance in the circuit board wiring that could cancel the usefulness of these low inductance components. Consult with the manufacturer of the load on specific decoupling requirements.

The shape of the output voltage waveform during a load transient that represents the worst case loading conditions will ultimately determine the number of output capacitors and their type. When this load transient is applied to the converter, most of the energy required by the load is initially delivered from the output capacitors. This is due to the finite amount of time required for the inductor current to slew up to the level of the output current required by the load. This phenomenon results in a temporary dip in the output voltage. At the very edge of the transient, the Equivalent Series Inductance (ESL) of each capacitor induces a spike that adds on top of the existing voltage drop due to the Equivalent Series Resistance (ESR).

After the initial spike, attributable to the ESR and ESL of the capacitors, the output voltage experiences sag. This sag is a direct consequence of the amount of capacitance on the output.

During the removal of the same output load, the energy stored in the inductor is dumped into the output capacitors. This energy dumping creates a temporary hump in the output voltage. This hump, as with the sag, can be attributed to the total amount of capacitance on the output. Figure 29 shows a typical response to a load transient.

FIGURE 29. TYPICAL TRANSIENT RESPONSE

The amplitudes of the different types of voltage excursions can be approximated by using the formulas in Equation 4:

$$\begin{aligned}\Delta V_{ESR} &= ESR \cdot I_{tran} & \Delta V_{ESL} &= ESL \cdot \frac{di_{tran}}{dt} \\ \Delta V_{SAG} &= \frac{L_{out} \cdot I_{tran}^2}{C_{out} \cdot (V_{in} - V_{out})} \\ \Delta V_{HUMP} &= \frac{L_{out} \cdot I_{tran}^2}{C_{out} \cdot V_{out}}\end{aligned}\quad (EQ. 4)$$

where

$I_{tran}$  = Output Load Current Transient

$C_{out}$  = Total Output Capacitance

In a typical converter design, the ESR of the output capacitor bank dominates the transient response. The ESR and the ESL are typically the major contributing factors in determining the output capacitance. The number of output capacitors can be determined by using Equation 5, which relates the ESR and ESL of the capacitors to the transient load step and the voltage limit ( $\Delta V_o$ ):

$$\text{Number of Caps} = \frac{ESL \cdot \frac{di_{tran}}{dt} + ESR \cdot I_{tran}}{\Delta V_o} \quad (EQ. 5)$$

If  $\Delta V_{SAG}$  and/or  $\Delta V_{HUMP}$  are found to be too large for the output voltage limits, then the amount of capacitance may need to be increased. In this situation, a trade off between output inductance and output capacitance may be necessary.

The ESL of the capacitors, which is an important parameter in Equations 4 and 5, is not usually listed in databooks. Practically, it can be approximated if an impedance vs frequency curve is given for a specific capacitor (C):

$$ESL = \frac{1}{C(2 \cdot \pi \cdot f_{res})^2} \quad (EQ. 6)$$

where  $f_{res}$  is the frequency where the lowest impedance is achieved (resonant frequency).

The ESL of the capacitors becomes a concern when designing circuits that supply power to loads with high rates of change in the current.

### Output Inductor Selection

The output inductor is selected to meet the output voltage ripple requirements and minimize the converter's response time to the load transient. The inductor value determines the converter's ripple current and the ripple voltage is a function of the ripple current. The ripple voltage and current are approximated by Equation 7:

$$\Delta I = \frac{V_{IN} - V_{OUT}}{F_s \times L} \times \frac{V_{OUT}}{V_{IN}} \quad \Delta V_{OUT} = \Delta I \times ESR \quad (EQ. 7)$$

Increasing the value of inductance reduces the ripple current and voltage. However, the large inductance values reduce the

converter's response time to a load transient. Use  $\Delta I$  of approximately 30% of  $I_{OUT}$  is a good compromise.

One of the parameters limiting the converter's response to a load transient is the time required to change the inductor current. Given a sufficiently fast control loop design, the ISL8560 will provide either 0% or 100% duty cycle in response to a load transient. The response time is the time required to slew the inductor current from an initial current value to the transient current level. During this interval the difference between the inductor current and the transient current level must be supplied by the output capacitor. Minimizing the response time can minimize the output capacitance required.

The response time to a transient is different for the application of load and the removal of load. Equation 8 gives the approximate response time interval for application and removal of a transient load:

$$t_{RISE} = \frac{L \times I_{TRAN}}{V_{IN} - V_{OUT}} \quad t_{FALL} = \frac{L \times I_{TRAN}}{V_{OUT}} \quad (EQ. 8)$$

where:  $I_{TRAN}$  is the transient load current step,  $t_{RISE}$  is the response time to the application of load, and  $t_{FALL}$  is the response time to the removal of load. The worst case response time can be either at the application or removal of load. Be sure to check both of these equations at the minimum and maximum output levels for the worst case response time.

### Rectifier Selection

Current circulates from ground to the junction of the MOSFET and the inductor when the high-side switch is off. As a consequence, the polarity of the switching node is negative with respect to ground. This voltage is approximately -0.5V (a Schottky diode drop) during the off time. The rectifier's rated reverse breakdown voltage must be at least equal to the maximum input voltage, preferably with a 20% derating factor. The power dissipation is:

$$P_D [W] = I_{OUT} \cdot V_D \cdot \left(1 - \frac{V_{OUT}}{V_{IN}}\right) \quad (EQ. 9)$$

where  $V_D$  is the voltage of the Schottky diode = 0.5V to 0.7V

### Input Capacitor Selection

Use a mix of input bypass capacitors to control the voltage overshoot across the VIN's pin. Use small ceramic capacitors for high frequency decoupling and bulk capacitors to supply the current needed each time the upper MOSFET turns on. Place the small ceramic capacitors physically close to the VIN and PGND pins.

The important parameters for the bulk input capacitance are the voltage rating and the RMS current rating. For reliable operation, select bulk capacitors with voltage and current ratings above the maximum input voltage and largest RMS current required by the circuit. Their voltage rating should be at

least 1.25 times greater than the maximum input voltage, while a voltage rating of 1.5 times is a conservative guideline. For most cases, the RMS current rating requirement for the input capacitor of a buck regulator is approximately 1/2 the DC load current.

The maximum RMS current through the input capacitors may be closely approximated through Equation 10:

$$\sqrt{\frac{V_{OUT}}{V_{IN}} \times \left( I_{OUT_{MAX}}^2 \times \left( 1 - \frac{V_{OUT}}{V_{IN}} \right) + \frac{1}{12} \times \left( \frac{V_{IN} - V_{OUT}}{L \times f_{OSC}} \times \frac{V_{OUT}}{V_{IN}} \right)^2 \right)} \quad (\text{EQ. 10})$$

For a through hole design, several electrolytic capacitors may be needed. For surface mount designs, solid tantalum capacitors can be used, but caution must be exercised with regard to the capacitor surge current rating. These capacitors must be capable of handling the surge-current at power-up. Some capacitor series available from reputable manufacturers are surge current tested.

### Feedback Compensation

Figure 30 highlights the voltage-mode control loop for a synchronous-rectified buck converter. The output voltage ( $V_{OUT}$ ) is regulated to the Reference voltage level. The error amplifier output ( $V_{E/A}$ ) is compared with the oscillator (OSC) triangular wave to provide a pulse-width modulated (PWM) wave with an amplitude of  $V_{IN}$  at the LX node. The PWM wave is smoothed by the output filter ( $L_O$  and  $C_O$ ).

The modulator transfer function is the small-signal transfer function of  $V_{OUT}/V_{E/A}$ . This function is dominated by a DC Gain and the output filter ( $L_O$  and  $C_O$ ), with a double pole break frequency at  $f_{LC}$  and a zero at  $f_{ESR}$ . The DC Gain of the modulator is simply the input voltage ( $V_{IN}$ ) divided by the peak-to-peak oscillator voltage  $\Delta V_{OSC}$ . The ISL8560 incorporates a feed forward loop that accounts for changes in the input voltage. This maintains a constant modulator gain.

### Modulator Break Frequency Equations

$$f_{LC} = \frac{1}{2\pi \times \sqrt{L_O \times C_O}} \quad f_{ESR} = \frac{1}{2\pi \times ESR \times C_O} \quad (\text{EQ. 11})$$

The compensation network consists of the transconductance amplifier (internal to the ISL8560) and the impedance networks  $Z_{IN}$  and  $Z_{FB}$ . The goal of the compensation network is to provide a closed loop transfer function with the highest OdB crossing frequency ( $f_{0dB}$ ) and adequate phase margin. Phase margin is the difference between the closed loop phase at  $f_{0dB}$  and  $180^\circ$ . The equations in the following section relate the compensation network's poles, zeros and gain to the components ( $R_2$ ,  $R_3$ ,  $R_4$ ,  $R_6$ ,  $C_{10}$ ,  $C_6$ , and  $C_7$ ) in Figure 30. Use these guidelines for locating the poles and zeros of the compensation network:

1. Pick Gain ( $R_3 g_m / (R_2 + R_3)$ ) for desired converter bandwidth.
2. Place 1<sup>ST</sup> Zero Below Filter's Double Pole ( $\sim 75\% f_{LC}$ ).

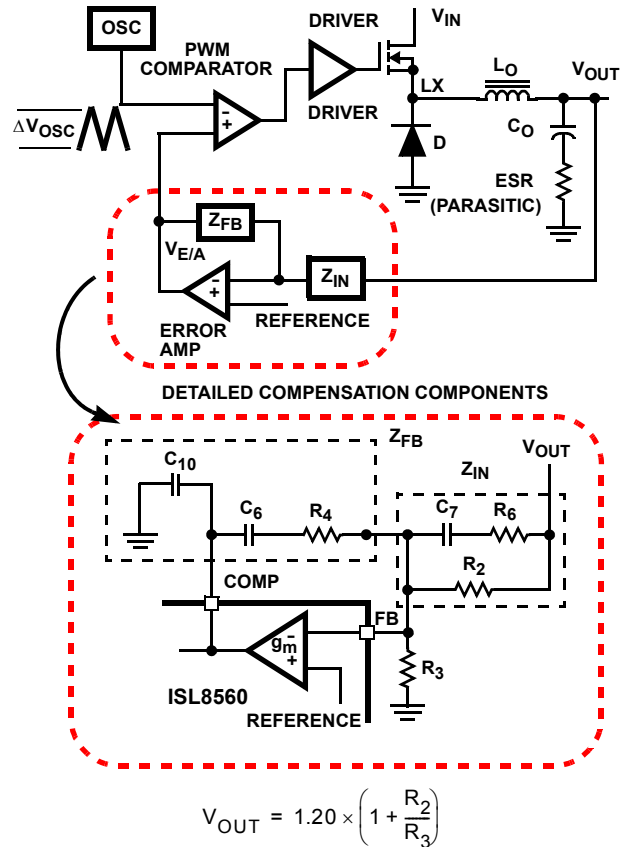

FIGURE 30. VOLTAGE-MODE BUCK CONVERTER COMPENSATION DESIGN AND OUTPUT VOLTAGE SELECTION

3. Place 2<sup>ND</sup> Zero at Filter's Double Pole.
4. Place 1<sup>ST</sup> Pole at the ESR Zero.
5. Place 2<sup>ND</sup> Pole at Half the Switching Frequency.
6. Check Gain against Error transconductance's Open-Loop Gain.
7. Estimate Phase Margin - Repeat if Necessary.

### Compensation Break Frequency Equations

$$f_{Z1} = \frac{1}{2\pi \cdot \frac{(R_4 \cdot g_m + 1)}{g_m} \cdot C_6} \quad f_{P1} = \frac{1}{2\pi R_6 \cdot C_7} \quad (EQ. 12)$$

$$f_{Z2} = \frac{1}{2\pi R_2 \cdot C_7} \quad f_{P2} = \frac{1}{2\pi R_4 \cdot C_{10}}$$

Assumption:  $R_6 \ll R_2$ ,  $R_6 \ll R_3$ , and  $C_{10} \ll C_6$ .

Figure 31 shows an asymptotic plot of the DC/DC converter's gain vs frequency. The actual Modulator Gain has a high gain peak due to the high Q factor of the output filter and is not shown in Figure 31. Using the guidelines on page 14 should give a Compensation Gain similar to the curve plotted. The open loop error amplifier gain bounds the compensation gain. Check the compensation gain at  $F_{P2}$  with the capabilities of the error amplifier. The Closed Loop Gain is constructed on the graph of Figure 31 by adding the Modulator Gain (in dB) to the Compensation Gain (in dB). This is equivalent to multiplying the modulator transfer function to the compensation transfer function and plotting the gain.

The compensation gain uses external impedance networks  $Z_{FB}$  and  $Z_{IN}$  to provide a stable, high bandwidth (BW) overall loop. A stable control loop has a gain crossing with  $-20\text{dB/decade}$  slope and a phase margin greater than  $45^\circ$ . Include worst case component variations when determining phase margin.

FIGURE 31. ASYMPTOTIC BODE PLOT OF CONVERTER GAIN

A more detailed explanation of voltage mode control of a buck regulator can be found in Tech Brief TB417, titled "Designing Stable Compensation Networks for Single Phase Voltage Mode Buck Regulators."

### Layout Considerations

Layout is very important in high frequency switching converter design. With power devices switching efficiently between 100kHz and 600kHz, the resulting current transitions from one device to another cause voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, radiate noise into the circuit, and lead to device overvoltage stress. Careful component layout and printed circuit board design minimizes these voltage spikes.

As an example, consider the turn-off transition of the control MOSFET. Prior to turn-off, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is picked up by the freewheeling Schottky diode. Any parasitic inductance in the switched current path generates a large voltage spike during the switching interval. Careful component selection, tight layout of the critical components, and short, wide traces minimizes the magnitude of voltage spikes.

There are two sets of critical components in the ISL8560 switching converter. The switching components are the most critical because they switch large amounts of energy, and therefore tend to generate large amounts of noise. Next are the small signal components which connect to sensitive nodes or supply critical bypass current and signal coupling.

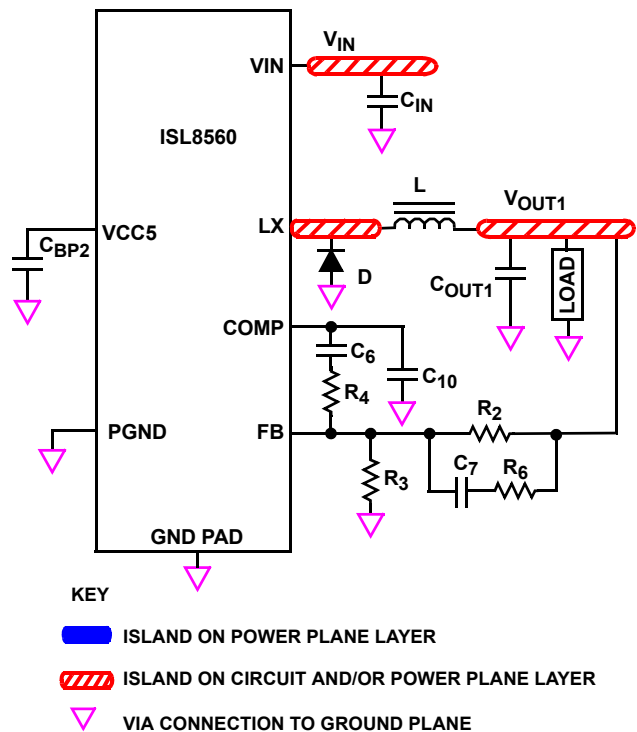

FIGURE 32. PRINTED CIRCUIT BOARD POWER PLANES AND ISLANDS

A multi-layer printed circuit board is recommended. Figure 32 shows the connections of the critical components in the converter. Note that capacitors  $C_{IN}$  and  $C_{OUT}$  could each represent numerous physical capacitors. Dedicate one solid layer, usually a middle layer of the PC board, for a ground plane and make all critical component ground connections with vias to this layer. Dedicate another solid layer as a power plane and break this plane into smaller islands of common voltage levels. Keep the metal runs from the LX terminals to the output inductor short. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the LX nodes. Use the remaining printed circuit layers for small signal wiring.

In order to dissipate heat generated by the internal LDO and other power components, the ground pad at the bottom of the device should be connected to the ground plane through at least nine vias. This allows the heat to move away from the IC and also ties the pad to the ground plane through a low impedance path.

The switching components should be placed close to the ISL8560 first. Minimize the length of the connections between the input capacitors,  $C_{IN}$ . Make the PGND and the output capacitors as short as possible.

NOTE: It is recommended that any applications with input voltage greater than 30VDC should be polymer coated to meet Intersil's IPC-2221 creepage and clearance specification.

**NOTES:**

1. Dimensioning and tolerancing conform to ASME Y14.5-1994.
2. N is the number of terminals.
3. Nd and Ne refer to the number of terminals on each D and E.
4. All dimensions are in millimeters. Angles are in degrees.
5. Dimension b applies to the metallized terminal and is measured between 0.15mm and 0.30mm from the terminal tip.
6. The configuration of the pin #1 identifier is optional, but must be located within the zone indicated. The pin #1 identifier may be either a mold or mark feature.
7. Dimensions D2 and E2 are for the exposed pads which provide improved electrical and thermal performance.
8. Nominal dimensions are provided to assist with PCB Land Pattern Design efforts, see Intersil Technical Brief TB389.
9. Features and dimensions A2, A3, D1, E1, P &  $\theta$  are present when Anvil singulation method is used and not present for saw singulation.
10. Depending on the method of lead termination at the edge of the package, a maximum 0.15mm pull back (L1) maybe present. L minus L1 to be equal to or greater than 0.3mm.
