

# **MIC2571**

### The Infinite Bandwidth Company<sup>™</sup>

### **General Description**

Micrel's MIC2571 is a micropower boost switching regulator that operates from one alkaline, nickel-metal-hydride cell, or lithium cell.

The MIC2571 accepts a positive input voltage between 0.9V and 15V. Its typical no-load supply current is 120µA.

The MIC2571 is available in selectable fixed output or adjustable output versions. The MIC2571-1 can be configured for 2.85V, 3.3V, or 5V by connecting one of three separate feedback pins to the output. The MIC2571-2 can be configured for an output voltage ranging between its input voltage and 36V, using an external resistor network.

The MIC2571 has a fixed switching frequency of 20kHz. An external SYNC connection allows the switching frequency to be synchronized to an external signal.

The MIC2571 requires only four components (diode, inductor, input capacitor and output capacitor) to implement a boost regulator. A complete regulator can be constructed in a 0.3 in $^2$  area.

All versions are available in an 8-lead MSOP with an operating range from  $-40^{\circ}$ C to  $+85^{\circ}$ .

# **Single-Cell Switching Regulator**

### **Final Information**

### **Features**

- Operates from a single-cell supply 0.9V to 15V operation
- 120µA typical quiescent current
- Complete regulator fits 0.3 in<sup>2</sup> area
- 2.85V/3.3V/5V selectable output voltage (MIC2571-1)
- Adjustable output up to 36V (MIC2571-2)
- 1A current limited pass element
- Frequency synchronization input
- 8-lead MSOP package

# **Applications**

- Pagers
- LCD bias generator
- Battery-powered, hand-held instruments
- Palmtop computers
- Remote controls
- **Detectors**
- Battery Backup Supplies

### **Typical Applications**

### **Single-Cell to 3.3V DC-to-DC Converter**

### **Ordering Information**

\* Externally selectable for 2.85V, 3.3V, or 5V

# **Pin Configuration**

**8-Lead MSOP (MM)**

### **Pin Description**

† Example: (-1) indicates the pin description is applicable to the MIC2571-1 only.

### **Functional Description**

The MIC2571 switch-mode power supply (SMPS) is a gated oscillator architecture designed to operate from an input voltage as low as 0.9V and provide a high-efficiency fixed or adjustable regulated output voltage. One advantage of this architecture is that the output switch is disabled whenever the output voltage is above the feedback comparator threshold thereby greatly reducing quiescent current and improving efficiency, especially at low output currents.

Refer to the Block Diagrams for the following discription of typical gated oscillator boost regulator function.

The bandgap reference provides a constant 0.22V over a wide range of input voltage and junction temperature. The comparator senses the output voltage through an internal or external resistor divider and compares it to the bandgap reference voltage.

When the voltage at the inverting input of the comparator is below 0.22V, the comparator output is high and the output of the oscillator is allowed to pass through the AND gate to the output driver and output switch. The output switch then turns on and off storing energy in the inductor. When the output switch is on (low) energy is stored in the inductor; when the switch is off (high) the stored energy is dumped into the output capacitor which causes the output voltage to rise.

When the output voltage is high enough to cause the comparator output to be low (inverting input voltage is above 0.22V) the AND gate is disabled and the output switch remains off (high). The output switch remains disabled until the output voltage falls low enough to cause the comparator output to go high.

There is about 6mV of hysteresis built into the comparator to prevent jitter about the switch point. Due to the gain of the feedback resistor divider the voltage at  $V_{\text{OUT}}$  experiences about 120mV of hysteresis for a 5V output.

### **Appications Information**

### **Oscillator Duty Cycle and Frequency**

The oscillator duty cycle is set to 67% which is optimized to provide maximum load current for output voltages approximately 3× larger than the input voltage. Other output voltages are also easily generated but at a small cost in efficiency. The fixed oscillator frequency (options -1 and -2) is set to 20kHz.

### **Output Waveforms**

The voltage waveform seen at the collector of the output switch (SW pin) is either a continuous value equal to  $V_{IN}$  or a switching waveform running at a frequency and duty cycle set by the oscillator. The continuous voltage equal to  $V_{IN}$ happens when the voltage at the output  $(V_{\text{OUT}})$  is high enough to cause the comparator to disable the AND gate. In this state the output switch is off and no switching of the inductor occurs. When  $V_{\text{OUT}}$  drops low enough to cause the comparator output to change to the high state the output switch is driven by the oscillator. See Figure 1 for typical voltage waveforms in a boost application.

**Figure 1. Typical Boost Regulator Waveforms**

#### **Synchronization**

The SYNC pin is used to synchronize the MIC2571 to an external oscillator or clock signal. This can reduce system noise by correlating switching noise with a known system frequency. When not in use, the SYNC pin should be grounded to prevent spurious circuit operation. A falling edge at the SYNC input triggers a one-shot pulse which resets the oscillator. It is possible to use the SYNC pin to generate oscillator duty cycles from approximately 20% up to the nominal duty cycle.

#### **Current Limit**

Current limit for the MIC2571 is internally set with a resistor. It functions by modifying the oscillator duty cycle and frequency. When current exceeds 1.2A, the duty cycle is reduced (switch on-time is reduced, off-time is unaffected) and the corresponding frequency is increased. In this way less time is available for the inductor current to build up while maintaining the same discharge time. The onset of current limit is soft rather than abrupt but sufficient to protect the inductor and output switch from damage. Certain combinations of input voltage, output voltage and load current can cause the inductor to go into a continuous mode of operation. This is what happens when the inductor current can not fall to zero and occurs when:

**Figure 2. Current Limit Behavior**

Figure 2 shows an example of inductor current in the continuous mode with its associated change in oscillator frequency and duty cycle. This situation is most likely to occur with relatively small inductor values, large input voltage variations and output voltages which are less than ~3× the input voltage. Selection of an inductor with a saturation threshold above 1.2A will insure that the system can withstand these conditions.

#### **Inductors, Capacitors and Diodes**

The importance of choosing correct inductors, capacitors and diodes can not be ignored. Poor choices for these components can cause problems as severe as circuit failure or as subtle as poorer than expected efficiency.

#### **Inductors**

Inductors must be selected such that they do not saturate under maximum current conditions. When an inductor saturates, its effective inductance drops rapidly and the current can suddenly jump to very high and destructive values.

Figure 3 compares inductors with currents that are correct and unacceptable due to core saturation. The inductors have the same nominal inductance but Figure 3b has a lower saturation threshold. Another consideration in the selection of inductors is the radiated energy. In general, toroids have the best radiation characteristics while bobbins have the worst. Some bobbins have caps or enclosures which significantly reduce stray radiation.

The last electrical characteristic of the inductor that must be considered is ESR (equivalent series resistance). Figure 3c shows the current waveform when ESR is excessive. The normal symptom of excessive ESR is reduced power transfer efficiency. Note that inductor ESR can be used to the designers advantage as reverse battery protection (current limit) for the case of relatively low output power one-cell designs. The potential for very large and destructive currents exits if a battery in a one-cell application is inserted backwards into the circuit. In some applications it is possible to limit the current to a nondestructive (but still battery draining) level by choosing a relatively high inductor ESR value which does not affect normal circuit performance.

#### **Capacitors**

It is important to select high-quality, low ESR, filter capacitors for the output of the regulator circuit. High ESR in the output capacitor causes excessive ripple due to the voltage drop across the ESR. A triangular current pulse with a peak of 500mA into a 200mΩ ESR can cause 100mV of ripple at the output due the capacitor only. Acceptable values of ESR are typically in the 50mΩ range. Inexpensive aluminum electrolytic capacitors usually are the worst choice while tantalum capacitors are typically better. Figure 4 demonstrates the effect of capacitor ESR on output ripple voltage.

**Figure 4. Output Ripple**

### **Output Diode**

Finally, the output diode must be selected to have adequate reverse breakdown voltage and low forward voltage at the application current. Schottky diodes typically meet these requirements.

Standard silicon diodes have forward voltages which are too large except in extremely low power applications. They can also be very slow, especially those suited to power rectification such as the 1N400x series, which affects efficiency.

#### **Inductor Behavior**

The inductor is an energy storage and transfer device. Its behavior (neglecting series resistance) is described by the following equation:

$$
I = \frac{V}{L} \times t
$$

where:

 $V =$  inductor voltage  $(V)$ 

 $L =$  inductor value (H)

$$
t = \text{time (s)}
$$

 $I =$  inductor current  $(A)$ 

If a voltage is applied across an inductor (initial current is zero) for a known time, the current flowing through the inductor is a linear ramp starting at zero, reaching a maximum value at the end of the period. When the output switch is on, the voltage across the inductor is:

$$
V_1 = V_{IN} - V_{SAT}
$$

When the output switch turns off, the voltage across the inductor changes sign and flies high in an attempt to maintain a constant current. The inductor voltage will eventually be clamped to a diode drop above  $V_{\text{OUT}}$ . Therefore, when the output switch is off, the voltage across the inductor is:

$$
V_2 = V_{OUT} + V_{DIODE} - V_{IN}
$$

For normal operation the inductor current is a triangular waveform which returns to zero current (discontinuous mode) at each cycle. At the threshold between continuous and discontinuous operation we can use the fact that  $I_1 = I_2$  to get:

$$
V_1 \times t_1 = V_2 \times t_2
$$
  

$$
\frac{V_1}{V_2} = \frac{t_2}{t_1}
$$

This relationship is useful for finding the desired oscillator duty cycle based on input and output voltages. Since input voltages typically vary widely over the life of the battery, care must be taken to consider the worst case voltage for each parameter. For example, the worst case for  $\mathsf{t}_1$  is when  $\mathsf{V}_{\mathsf{IN}}$  is at its minimum value and the worst case for  $\mathsf{t}_2$  is when  $\mathsf{V}_{\mathsf{IN}}$  is at its maximum value (assuming that  $V_{\text{OUT}}$ ,  $V_{\text{DIODE}}$  and  $V_{\text{SAT}}$ do not change much).

To select an inductor for a particular application, the worst case input and output conditions must be determined. Based on the worst case output current we can estimate efficiency and therefore the required input current. Remember that this is power conversion, so the worst case average input current will occur at maximum output current and minimum input voltage.

Average I<sub>IN(max)</sub> = 
$$
\frac{V_{OUT} \times I_{OUT(max)}}{V_{IN(min)} \times Efficiency}
$$

Referring to Figure 1, it can be seen the peak input current will be twice the average input current. Rearranging the inductor equation to solve for L:

L = 
$$
\frac{V}{I} \times t_1
$$
  
\nL =  $\frac{V_{IN(min)}}{2 \times Average I_{IN(max)}} \times t_1$   
\nwhere t<sub>1</sub> =  $\frac{duty cycle}{f_{OSC}}$ 

To illustrate the use of these equations a design example will be given:

Assume:

$$
MIC2571-1 \text{ (fixed oscillator)}
$$
\n
$$
V_{OUT} = 5V
$$
\n
$$
I_{OUT(max)} = 5mA
$$
\n
$$
V_{IN(min)} = 1.0V
$$
\n
$$
efficiency = 75\%.
$$
\n
$$
Average I_{IN(max)} = \frac{5V \times 5mA}{5M}
$$

Average I<sub>IN(max)</sub> = 
$$
\frac{5V \times 5mA}{1.0V \times 0.75} = 33.3mA
$$
  
L = 
$$
\frac{1.0V \times 0.7}{2 \times 33.3mA \times 20kHz}
$$
  
L = 525µH

Use the next lowest standard value of inductor and verify that it does not saturate at a current below about 75mA  $(< 2 \times 33.3$ mA).
