## Phase-Locked Loop with VCO And Lock Detector

### Type Features:

- Center frequency of 18 MHz (typ.) at  $V_{CC} = 5\text{ V}$
- Choice of two phase comparators: Exclusive-OR, Edge-triggered JK flip-flop
- Excellent VCO frequency linearity
- VCO-inhibit control for ON/OFF keying and for low standby power consumption
- Minimal frequency drift
- Zero voltage offset due to op-amp buffer
- Operating power-supply voltage range: VCO section 3 V to 6 V; Digital section 2 V to 6 V

The RCA-CD54/74HC7046A and CD54/74HCT7046A high-speed silicon-gate CMOS devices, specified in compliance with JEDEC Standard No. 7A, are phase-locked-loop (PLL) circuits that contain a linear voltage-controlled oscillator (VCO), two-phase comparators (PC1, PC2), and a lock detector. A signal input and a comparator input are common to each comparator. The lock detector gives a HIGH level at pin 1 (LD) when the PLL is locked. The lock detector capacitor must be connected between pin 15 ( $C_{LD}$ ) and pin 8 (Gnd). For a frequency range of 100 kHz to 10 MHz, the lock detector capacitor should be 1000 pF to 10 pF, respectively.

The signal input can be directly coupled to large voltage signals, or indirectly coupled (with a series capacitor) to small voltage signals. A self-bias input circuit keeps small voltage signals within the linear region of the input amplifiers. With a passive low-pass filter, the 7046A forms a second-order loop PLL. The excellent VCO linearity is achieved by the use of linear op-amp techniques.

The CD54HC7046A and CD54HCT7046A are supplied in 16-lead ceramic dual-in-line packages (F suffix). The CD74HC7046A and CD74HCT7046A are supplied in 16-lead plastic dual-in-line packages (E suffix) and in 16-lead small-outline plastic dual-in-line packages (M suffix). Both types are also available in chip form (H suffix).

### Applications:

- FM modulation and demodulation
- Frequency synthesis and multiplication
- Frequency discrimination
- Tone decoding
- Data synchronization and conditioning
- Voltage-to-frequency conversion
- Motor-speed control
- For additional information, refer to application note, ICAN-8823.

### Family Features:

- Fanout (over temperature range); Standard outputs - 10 LSTTL loads; Bus driver outputs - 15 LSTTL loads
- Wide operating temperature range: CD74HC/HCT:  $-40$  to  $+125^\circ\text{C}$
- Balanced propagation delay and transition times
- Significant power reduction compared to LSTTL logic ICs
- Alternate source: Philips/Signetics
- CD54HC/CD74HC types: 2 V to 6 V operation; High noise immunity:  $N_{IL}=30\%$ ,  $N_{IH}=30\%$  of  $V_{CC}$ ; @ $V_{CC}=5\text{ V}$
- CD54HCT/CD74HCT types: 4.5 V to 5.5 V operation; Direct LSTTL input logic compatibility:  $V_{IL}=0.8\text{ V max.}$ ,  $V_{IH}=2\text{ V min.}$ ; CMOS input compatibility:  $I_L \leq 1\ \mu\text{A}$  @  $V_{OL}$ ,  $V_{OH}$

Fig. 1 - Logic diagram.

## GENERAL DESCRIPTION

### VCO

The VCO requires one external capacitor C1 (between C1A and C1B) and one external resistor R1 (between R1 and Gnd) or two external resistors R1 and R2 (between R1 and Gnd, and R2 and Gnd). Resistor R1 and capacitor C1 determine the frequency range of the VCO. Resistor R2 enables the VCO to have a frequency offset if required. See logic diagram, Fig. 1.

The high input impedance of the VCO simplifies the design of low-pass filters by giving the designer a wide choice of resistor/capacitor ranges. In order not to load the low-pass filter, a demodulator output of the VCO input voltage is provided at pin 10 (DEM<sub>OUT</sub>). In contrast to conventional techniques where the DEM<sub>OUT</sub> voltage is one threshold voltage lower than the VCO input voltage, here the DEM<sub>OUT</sub> voltage equals that of the VCO input. If DEM<sub>OUT</sub> is used, a load resistor (R<sub>S</sub>) should be connected from DEM<sub>OUT</sub> to Gnd; if unused, DEM<sub>OUT</sub> should be left open. The VCO output (VCO<sub>OUT</sub>) can be connected directly to the comparator input (COMP<sub>IN</sub>), or connected via a frequency divider. The VCO output signal has a guaranteed duty factor of 50%. A LOW level at the inhibit input (INH) enables the VCO, while a HIGH level disables the VCO to minimize standby power consumption.

### Phase Comparators

The signal input (SIG<sub>IN</sub>) can be directly coupled to the self-biasing amplifier at pin 14, provided that the signal swing is between the standard HC family input logic levels. Capacitive coupling is required for signals with smaller swings.

### Phase Comparator 1 (PC1)

This is an Exclusive-OR network. The signal and comparator input frequencies (f<sub>i</sub>) must have a 50% duty factor to obtain the maximum locking range. The transfer characteristic of PC1, assuming ripple (f<sub>r</sub> = 2f<sub>i</sub>) is suppressed, is:

$V_{\text{DEMODOUT}} = (V_{\text{CC}}/\pi) (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$  where V<sub>DEMODOUT</sub> is the demodulator output at pin 10; V<sub>DEMODOUT</sub> = V<sub>PC1OUT</sub> (via low-pass filter).

The average output voltage from PC1, fed to the VCO input via the low-pass filter and seen at the demodulator output at pin 10 (V<sub>DEMODOUT</sub>), is the resultant of the phase differences of signals (SIG<sub>IN</sub>) and the comparator input (COMP<sub>IN</sub>) as shown in Fig. 2. The average of V<sub>DEM</sub> is equal to ½ V<sub>CC</sub> when there is no signal or noise at SIG<sub>IN</sub>, and with this input the VCO oscillates at the center frequency (f<sub>c</sub>). Typical waveforms for the PC1 loop locked at f<sub>c</sub> are shown in Fig. 3.

The frequency capture range (2f<sub>c</sub>) is defined as the frequency range of input signals on which the PLL will lock if it was initially out-of-lock. The frequency lock range (2f<sub>l</sub>) is defined as the frequency range of input signals on which the loop will stay locked if it was initially in lock. The capture range is smaller or equal to the lock range.

With PC1, the capture range depends on the low-pass filter characteristics and can be made as large as the lock range. This configuration retains lock behavior even with very noisy input signals. Typical of this type of phase comparator is that it can lock to input frequencies close to the harmonics of the VCO center frequency.

# CD54/74HC7046A CD54/74HCT7046A

Fig. 2 - Phase comparator 1: average output voltage vs input phase difference:

$$V_{\text{DEMOUT}} = V_{\text{PC1OUT}} = (V_{\text{CC}}/\pi) (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}});$$

$$\phi_{\text{DEMOUT}} = (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}}).$$

Fig. 3 - Typical waveforms for PLL using phase comparator 1, loop locked at  $f_0$ .

## Phase Comparator 2 (PC2)

This is a positive edge-triggered phase and frequency detector. When the PLL is using this comparator, the loop is controlled by positive signal transitions and the duty factors of SIG<sub>IN</sub> and COMP<sub>IN</sub> are not important. PC2 comprises two D-type flip-flops, control-gating and a 3-state output stage. The circuit functions as an up-down counter (Fig. 1) where SIG<sub>IN</sub> causes an up-count and COMP<sub>IN</sub> a down-count. The transfer function of PC2, assuming ripple ( $f_r = f_0$ ) is suppressed, is:

$V_{\text{DEMOUT}} = (V_{\text{CC}}/4\pi) (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}})$  where  $V_{\text{DEMOUT}}$  is the demodulator output at pin 10;  $V_{\text{DEMOUT}} = V_{\text{PC2OUT}}$  (via low-pass filter).

The average output voltage from PC2, fed to the VCO via the low-pass filter and seen at the demodulator output at pin 10 ( $V_{\text{DEMOUT}}$ ), is the resultant of the phase differences of SIG<sub>IN</sub> and COMP<sub>IN</sub> as shown in Fig. 4. Typical waveforms for the PC2 loop locked at  $f_0$  are shown in Fig. 5.

When the frequencies of SIG<sub>IN</sub> and COMP<sub>IN</sub> are equal but the phase of SIG<sub>IN</sub> leads that of COMP<sub>IN</sub>, the p-type output driver at PC2<sub>OUT</sub> is held "ON" for a time corresponding to the phase difference ( $\phi_{\text{DEMOUT}}$ ). When the phase of SIG<sub>IN</sub> lags that of COMP<sub>IN</sub>, the n-type driver is held "ON".

When the frequency of SIG<sub>IN</sub> is higher than that of COMP<sub>IN</sub>, the p-type output driver is held "ON" for most of the input signal cycle time, and for the remainder of the cycle both n- and p-type drivers are "OFF" (3-state). If the SIG<sub>IN</sub> frequency is lower than the COMP<sub>IN</sub> frequency, then it is the n-type driver that is held "ON" for most of the cycle. Subsequently, the voltage at the capacitor (C2) of the low-pass filter connected to PC2<sub>OUT</sub> varies until the signal and comparator inputs are equal in both phase and frequency. At this stable point the voltage on C2 remains constant as the PC2 output is in 3-state and the VCO input at pin 9 is a high impedance.

Fig. 4 - Phase comparator 2: average output voltage vs input phase difference:

$$V_{\text{DEMOUT}} = V_{\text{PC2OUT}} = (V_{\text{CC}}/4\pi) (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}});$$

$$\phi_{\text{DEMOUT}} = (\phi_{\text{SIGIN}} - \phi_{\text{COMPIN}}).$$

Fig. 5 - Typical waveforms for PLL using phase comparator 2, loop locked at  $f_0$ .

Thus, for PC2, no phase difference exists between SIG<sub>IN</sub> and COMP<sub>IN</sub> over the full frequency range of the VCO. Moreover, the power dissipation due to the low-pass filter is reduced because both p- and n-type drivers are "OFF" for most of the signal input cycle. It should be noted that the PLL lock range for this type of phase comparator is equal to the capture range and is independent of the low-pass filter. With no signal present at SIG<sub>IN</sub>, the VCO adjusts, via PC2, to its lowest frequency.

## Lock Detector Theory of Operation

Detection of a locked condition is accomplished by a NOR gate and an envelope detector as shown in Fig. 6. When the PLL is in Lock, the output of the NOR gate is High and the lock detector output (Pin 1) is at a constant high level. As the loop tracks the signal on Pin 14 (signal in), the NOR gate outputs pulses whose widths represent the phase differences between the VCO and the input signal. The time between pulses will be approximately equal to the time constant of the VCO center frequency. During the rise time of the pulse, the diode across the 1.5-k $\Omega$  resistor is forward biased and the time constant in the path that charges the lock detector capacitor is

$$T = (150 \Omega \times C_{\text{LD}}).$$

During the fall time of the pulse the capacitor discharges through the 1.5 k $\Omega$  and the 150- $\Omega$  resistors and the channel resistance of the n-device of the NOR gate to ground

$$(T = (1.5 \text{ k}\Omega + 150 \Omega + R_{\text{n-channel}}) \times C_{\text{LD}}).$$

The waveform present at the capacitor resembles a sawtooth as shown in Fig. 7. The lock detector capacitor value is determined by the VCO center frequency. The typical range of capacitor for a frequency of 10 MHz is about 10 pF and for a frequency of 100 kHz is about 1000 pF. The chart in Fig. 8 can be used to select the proper lock detector capacitor value. As long as the loop remains locked and tracking, the

# CD54/74HC7046A CD54/74HCT7046A

level of the sawtooth will not go below the switching threshold of the Schmitt-trigger inverter. If the loop breaks lock, the width of the error pulse will be wide enough to allow the sawtooth waveform to go below threshold and a level change at the output of the Schmitt trigger will indicate a loss of lock, as shown in Fig. 9. The lock detector capacitor also acts to filter out small glitches that can occur when the loop is either seeking or losing lock.

**Note:** When using phase comparator 1, the detector will only indicate a lock condition on the fundamental frequency and not on the harmonics, which PC1 will also lock on. If a detection of lock is needed over the harmonic locking range of PC1, then the lock detector output must be OR-ed with the output of PC1.

#### APPLICATION INFORMATION

This information is a guide for the approximation of values of external components to be used with the 74HC/HCT7046A in a phase-lock-loop system.

References should be made to Fig. 11 through 21 and 27 through 32 as indicated in the table.

Values of the selected components should be within the following ranges:

- R1 > 3 k $\Omega$ ;
- R2 > 3 k $\Omega$ ;
- R1 || R2 parallel value > 2.7 k $\Omega$ ;
- C1 greater than 40 pF.

SUBJECT	PHASE COMPARATOR	DESIGN CONSIDERATIONS
VCO Frequency without extra offset (R2 = $\infty$ )	PC1 or PC2	<b>VCO Frequency Characteristic</b> The characteristics of the VCO operation are shown in Figs. 11-21.  <p style="text-align: center;"><i>Fig. 46 - Frequency characteristic of VCO operating without offset: f<sub>0</sub> = center frequency; 2f<sub>L</sub> = frequency lock range.</i></p>
	PC1	<b>Selection of R1 and C1</b> Given f <sub>0</sub> , determine the values of R1 and C1 using Figs. 11-15.
	PC2	Given f <sub>max</sub> and f <sub>0</sub> , determine the values of R1 and C1 using Figs. 11-15. To obtain 2f <sub>L</sub> : $2f_L \approx \frac{2(\Delta V_{COIN})}{R1C1}$ where $0.9 V < V_{COIN} < V_{CC} - 0.9 V$ is the range of $\Delta V_{COIN}$
VCO Frequency with extra offset (R2 > 3 k $\Omega$ )	PC1 or PC2	<b>VCO Frequency Characteristic</b> The characteristics of the VCO operation are shown in Figs. 27-30.  <p style="text-align: center;"><i>Fig. 47 - Frequency characteristic of VCO operating with offset: f<sub>0</sub> = center frequency; 2f<sub>L</sub> = frequency lock range.</i></p>
	PC1 or PC2	<b>Selection of R1, R2 and C1</b> Given f <sub>0</sub> and f <sub>L</sub> , offset frequency, f <sub>min</sub> , may be calculated from $f_{min} \approx f_0 - 1.6 f_L$ . Obtain the values of C1 and R2 by using Figs. 27-30. Calculate the value of R1 from the value of C1 and the product R1C1.

## APPLICATION INFORMATION (Con't'd)

SUBJECT	PHASE COMPARATOR	DESIGN CONSIDERATIONS
PLL Conditions with No Signal at the SIG <sub>IN</sub> Input	PC1	VCO adjusts to $f_o$ with $\phi_{\text{DEMOD}} = 90^\circ$ and $V_{\text{VCOIN}} = \frac{1}{2} V_{\text{CC}}$ (see Fig. 2).
	PC2	VCO adjusts to $f_o$ with $\phi_{\text{DEMOD}} = -360^\circ$ and $V_{\text{VCOIN}} = 0 \text{ V}$ (see Fig. 4).
PLL Frequency Capture Range	PC1 or PC2	<p><b>Loop Filter Component Selection</b></p> <p>(a) <math>\tau_1 = R_3 \times C_2</math>      (b) amplitude characteristic      (c) pole-zero diagram  A small capture range (<math>2f_c</math>) is obtained if <math>\tau &gt; 2f_c \approx (1/\pi) (2\pi f_c/\tau_1)^{1/2}</math>  <i>Fig. 48 - Simple loop filter for PLL without offset.</i></p> <p>(a) <math>\tau_2 = R_4 \times C_2</math>;      (b) amplitude characteristic      (c) pole-zero diagram  <math>\tau_3 = (R_3 + R_4) \times C_2</math>  <i>Fig. 49 - Simple loop filter for PLL with offset.</i></p>
PLL Locks on Harmonics at Center Frequency	PC1	Yes
	PC2	No
Noise Rejection at Signal Input	PC1	High
	PC2	Low
AC Ripple Content When PLL is Locked	PC1	$f_r = 2f_i$ , large ripple content at $\phi_{\text{DEMOD}} = 90^\circ$
	PC2	$f_r = f_i$ , small ripple content at $\phi_{\text{DEMOD}} = 0^\circ$

**Lock Detector Circuit**

The lock detector feature is very useful in data synchronization, motor speed control, and demodulation. By adjusting the value of the lock detector capacitor so that the lock output will change slightly before actually losing lock, the designer can create an "early warning" indication allowing corrective measures to be implemented. The reverse is also true, especially with motor speed controls, generators, and

clutches that must be set up before actual lock occurs or disconnected during loss of lock.

When using phase comparator 1, the detector will only indicate a lock condition on the fundamental frequency and not on the harmonics, which PC1 will lock on.
