

Synchronous Rectifier Driver

Features

- Provides constant and proper gate drive to power MOSFETs regardless of transformer output
- Minimizes loss due to power MOSFET body drain diode conduction
- Stand alone operation - no ties to primary side
- Schmitt trigger input with double pulse suppression allows operation in noisy environments
- High peak current drive capability - 2A
- High speed operation - 2MHz
- Adaptable to multiple topologies (such as single-ended forward, double-ended forward)

Product Summary

V _{dd}	5Vdc
I _{O+/-} (peak)	2A/2A
F _{max}	2MHz
Max lead time	500nsec

Description

The IR1175 is a high speed CMOS controller designed to drive N-channel power MOSFETs used as synchronous rectifiers in high current, high frequency forward converters with output voltages equal or below 5VDC. Schmitt trigger inputs with double pulse suppression allow the controller to operate in noisy environments. The circuit does not require any ties to the primary side and derives its operating power directly from the secondary. The circuit functions by anticipating transformer output transitions, then turns the power MOSFETs on or off before the transitions of the transformer to minimize body drain diode conduction and reduce associated losses. Turn on/off lead time can be adjusted to accommodate a variety of power MOSFET sizes and circuit conditions. The IR1175 also provides gate drive overlap/dead-time control via external components to further minimize diode conduction by nulling effects of secondary loop and device package inductance.

Lead Definitions and Assignments

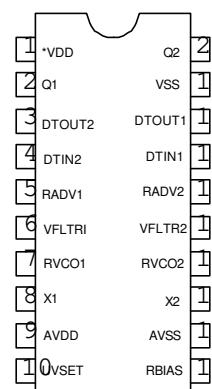

Symbol	Description
AVDD	Power - + 5 V _{DC} to MOSFET drivers
Q1	Output - gate drive for Q1 power MOSFET
DTOUT1	Output - sets dead time for Q1 output - used with DTIN1
DTIN1	Input - sets dead time for Q1 - used with DTOUT1
RADV1	Output - sets lead time (advance) for Q1
VFLTR1	Output - PLL loop filter for Q1 output
RVC01	Output - sets PLL center frequency for Q1 output
X1	Input - transformer input for Q1
VDD	Power - +5 Vdc for internal logic
UVSET	Input - sets UVLO+ If this pin is pulled below 1.25VDC externally, then both Q1 and Q2 outputs will be at Vss (disabled)
RBIAS	Output - connected to 69.8K +/- 1% resistor - sets operating current
AVSS	Ground for logic supply (AVDD)
X2	Input - transformer input for Q2
RVC02	Output - sets PLL center frequency for Q2 output
VFLTR2	Output - PLL loop filter for Q2
RADV2	Output - sets lead time (advance) for Q2
DTIN2	Input - sets dead time for Q2 - used with DTOUT2
DTOUT2	Output - sets dead time for Q2 - used with DTIN2
VSS	Ground for MOSFET driver supply (VDD)
Q2	Output - gate drive for Q2 power MOSFET

**Fig. 3 Gate drive characteristics and definitions****Phase Lock Loop Design Equations:**

1 - Resistor to set VCO Ceter Frequency:

$$R_{VCO} (K\Omega) = 143 \times [V_{chgpump}(V_{DC}) / f_{VCO}(KHz)] \times K_{VCO_dc}(KHz/Volt)$$

Example (A): Choose $V_{chgpump} = 1.5V$, desired frequency ($f_{VCO} = 300KHz$)

$$R_{VCO} = 143 \times [1.5 / 300] \times 62 \text{ Hz/Volt} = 44.33 K\Omega$$

2 - Small Signal gain for VCO:

$$K_{VCO_ac} (KHz/Volt) = 1E3 \times K_{VCO_dc} (KHz/Volt) / (7 \times R_{VCO}(K\Omega))$$

Example (B): Choosing same conditions as in example A:

$$K_{VCO_ac} = 1E3 \times 62 / (7 \times 44.33) = 199.9 \text{ KHz/volt}$$

3 -PLL Natural frequency:

$$\omega_n = 2\pi f_n (\text{kHz}) = \sqrt{I_{chpump} (\mu\text{A}) \times K_{vco_ac} (\text{kHz/V}) / C (\text{nF})}$$

Choose C_f such that $C_f = C/16$

4 -PLL Damping factor calculations:

$$P = \pi E_3 \times R_f (\text{kOhms}) \times C (\text{nF}) \times f_n (\text{kHz})$$

Typical value for P is 0.707. (Critically damped)

5 -Advance timing:

$$T_{adv} (\text{nsec}) = R_{ADV} (\text{kOhms}) * 10 - 10$$

Where R_{ADV} is resistance from R_{ADV1} or R_{ADV2} to ground.

Example C: $R_{ADV} = 10 \text{ kOhms}$ will result in $T_{adv} = 10 * 10 - 10 = 90 \text{ nsec}$.

6 -Dead time calculations:

$$T_d (\text{nsec}) = 0.69 * R_{dt} (\text{kOhms}) * C_{dt} (\text{pF}) + 5 \quad (\text{For } V_{dd} = 5 \text{ V})$$

Where R_{dt} is resistance between pins DTIN1 and DTOUT1 or DTIN2 and DTOUT2. C_{dt} is capacitance from DTIN1 or DTIN2 to ground.

Example D: $R_{dt} = 10 \text{ kOhms}$ and $C_{dt} = 22 \text{ pF}$ will result in: $T_d = 156.8 \text{ nsec}$
