

Galvanically isolated 4 A dual gate driver

Features

- High voltage rail up to 1200 V
- Driver current capability: 4 A sink/source @ 25 °C
- dV/dt transient immunity ± 100 V/ns
- Overall input-output propagation delay: 75 ns
- Separate sink and source option for easy gate driving configuration
- 4 A Miller CLAMP
- UVLO function
- Configurable interlocking function
- Dedicated SD and BRAKE pins
- Gate driving voltage up to 26 V
- 3.3 V, 5 V TTL/CMOS inputs with hysteresis
- Temperature shutdown protection
- Standby function
- 6 kV galvanic isolation
- Wide Body SO-36W
- UL 1577 recognized

Application

- Motor driver for industrial drives, factory automation, home appliances and fans
- 600/1200 V inverters
- Battery chargers
- Induction heating
- Welding
- UPS
- Power supply units
- DC-DC converters
- Power Factor Correction

Description

The **STGAP2HD** is a dual gate driver which provides galvanic isolation between each gate driving channel and the low voltage control and interface circuitry. The gate driver is characterized by 4 A current capability and rail-to-rail outputs, making it suitable for mid and high power applications such as power conversion and industrial motor driver inverters. The separated output pins allow to independently optimize turn-on and turn-off by using dedicated gate resistors, while the Miller CLAMP function allows avoiding gate spikes during fast commutations in half-bridge topologies. The device integrates protection functions: dedicated SD and BRAKE pins are available, UVLO and thermal shutdown are included to easily design high reliability systems. In half-bridge topologies the interlocking function prevents outputs from being high at the same time, avoiding shoot-through conditions in case of wrong logic input commands. The interlocking function can be disabled by a dedicated configuration pin, so to allow independent and parallel operation of the two channels. The input to output propagation delay results are contained within 75 ns, providing high PWM control accuracy. A standby mode is available in order to reduce idle power consumption.

6 Functional description

6.1 Gate driving power supply and UVLO

The STGAP2HD is a flexible and compact gate driver with 4 A output current and rail-to-rail outputs. The device allows to implement either unipolar or bipolar gate driving.

Figure 3. Power supply configuration for unipolar and bipolar gate driving

Undervoltage protection is available on VH_x supply pin. A fixed hysteresis sets the turn-off threshold, thus avoiding intermittent operation.

When VH_x voltage goes below the VH_{off} threshold, the output buffer goes into “safe state”. When VH_x voltage reaches the VH_{on} threshold, the device returns to normal operation and sets the output according to actual input pins status.

The VDD and VH_x supply pins must be properly filtered with local bypass capacitors. The use of capacitors with different values in parallel provides both local storage for impulsive current supply and high-frequency filtering. The best filtering is obtained by using low-ESR SMT ceramic capacitors, which are therefore recommended. A 100 nF ceramic capacitor must be placed as close as possible to each supply pin, and a second bypass capacitor with value in the range between 1 μ F and 10 μ F should be placed close to it.

6.2 Power-up, power-down and ‘safe state’

The following conditions define the “safe state”:

- GOFF = ON state
- GON = high impedance

Such conditions are maintained at power-up of the isolated side ($VH_x < VH_{on}$) and during whole device power-down phase ($VH < VH_{off}$), regardless of the value of the input pins.

The device integrates a structure which clamps the driver output to a voltage not higher than SafeClp when VH voltage is not high enough to actively turn the internal GOFF MOSFET on. If VH_x positive supply pin is floating or not supplied, the GOFF pin is therefore clamped to a voltage smaller than SafeClp.

If the supply voltage VDD of the control section of the device is not supplied, the output is put in safe state, and remains in such condition until the VDD voltage returns within operative conditions.

After power-up of both isolated and low voltage side the device output state depends on the input pins' status.

6.3 Control Inputs

The device is controlled through the following logic inputs:

- SD: active low shutdown input;
- BRAKE: active low brake input;
- INA, INB: active high logic inputs for channel A and channel B driver outputs;
- iLOCK: used to enable or disable the interlocking protection.

The operation of the driver IOs is described in [Table 9](#).

Table 9. Inputs truth table (applicable when device is not in UVLO or "safe state")

	Input pins ⁽¹⁾					Output pins	
	iLOCK	SD	BRAKE	INA	INB	GOUT_A	GOUT_B
	X	L	X	X	X	Low	Low
	X	H	L	X	X	Low	HIGH
	X	H	H	L	L	Low	Low
	X	H	H	H	L	HIGH	Low
	X	H	H	L	H	Low	HIGH
Interlocking	VDD	H	H	H	H	Low	Low
	GND	H	H	H	H	HIGH	HIGH

1. X: Don't care.

A deglitch filter allows input signals with duration shorter than t_{deglitch} to be ignored, thereby preventing noise spikes potentially present in the application from generating unwanted commutations.

6.4 Watchdog

The isolated HV side has a watchdog function in order to identify when it is not able to communicate with LV side, for example because the VDD of the LV side is not supplied. In this case the output of the driver is forced in "safe state" until communication link is properly established again.

6.5 Thermal shutdown protection

The device provides a thermal shutdown protection. When junction temperature reaches the TSD temperature threshold, the device is forced in "safe state". The device operation is restored as soon as the junction temperature is lower than TSD - Thys.

6.6 Standby function

In order to reduce the power consumption of both control interface and gate driving sides the device can be put in standby mode. In standby mode the quiescent current from VDD and VH_x supply pins is reduced to I_{QDDs} and I_{QHS_x} respectively, and the output remains in 'safe state' (the output is actively forced low).

The way to enter standby is to keep the SD low while keeping the other input pins (INA, INB and BRAKE) high ("standby" value) for a time longer than t_{STBY} . During standby the inputs can change from the "standby" value.

To exit standby, inputs must be put in any combination different from the "standby" value for a time longer than t_{stbyfilt} , and then in the "standby" value for a time t such that $t_{\text{WUP}} < t < t_{\text{STBY}}$.

When the input configuration is changed from the "standby" value, the output is enabled and set according to inputs state after a time t_{awake} .

Figure 4. Standby state sequences

Sequence to enter stand-by mode

Sequence to exit stand-by mode

6.7 Interlocking function

The interlocking function prevents outputs GOUT_A and GOUT_B from being high at the same time, regardless of the status of the input pins INA and INB. In half-bridge topologies this protection avoids shoot-through in case that wrong input signals are generated by the controller device. In case the status of INA and INB is such to require both channels to be ON at the same time, the driver turns both channels off. In some topologies it is required to allow both channels to be ON at the same time: this can be achieved by disabling the interlocking function through the iLOCK pin. The iLOCK pin shall be either connected to VDD, which enables the interlocking function, or to GND, which disables the interlocking function and allows parallel operation of Channel_A and Channel_B. Refer to Section 6.3 for complete logic inputs truth table.

7 Typical application diagram

Figure 5. Typical application diagram – half-bridge configuration

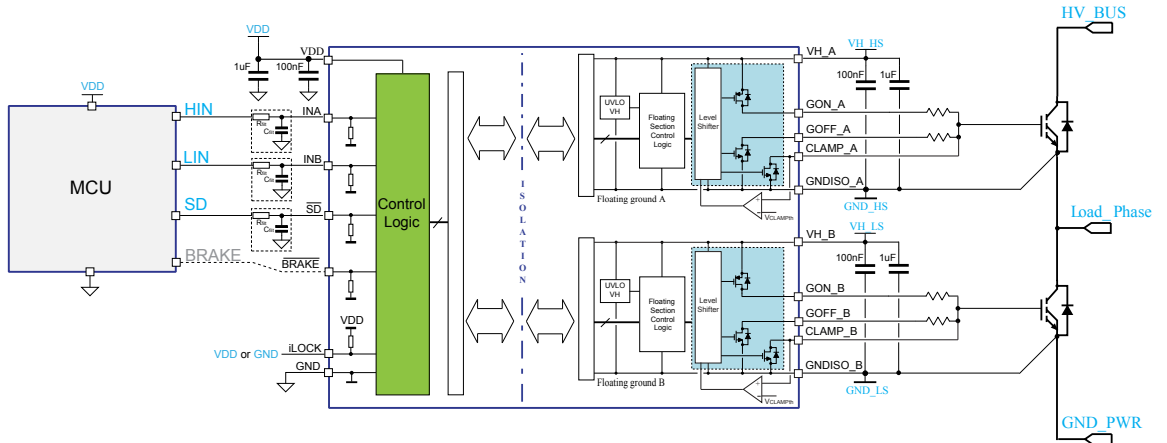

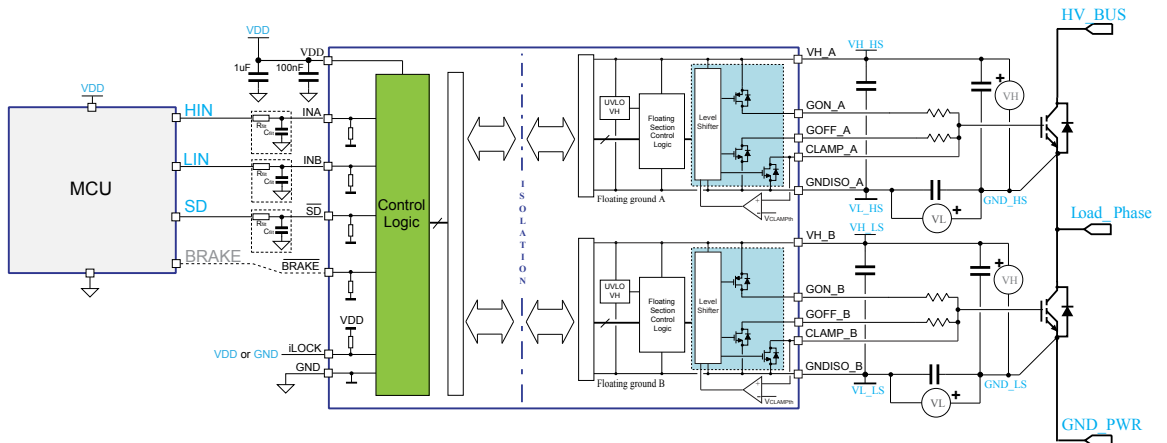

Figure 6. Typical application diagram – half-bridge configuration with negative gate driving

8 Layout

8.1 Layout guidelines and considerations

In order to optimize the PCB layout, the following considerations should be taken into account:

- SMD ceramic capacitors (or different types of low-ESR and low-ESL capacitors) must be placed close to each supply rail pin. A 100 nF capacitor must be placed between VDD and GND and between VH_x and GNDISO_x, as close as possible to device pins, in order to filter high-frequency noise and spikes. In order to provide local storage for pulsed current a second capacitor with value in the range between 1 μ F and 10 μ F should also be placed close to the supply pins.
 - As a good practice it is suggested to add filtering capacitors close to logic inputs of the device (INA, INB, BRAKE, SD), in particular for fast switching or noisy applications.
- The power transistors must be placed as close as possible to the gate driver, so to minimize the gate loop area and inductance that might bring about noise or ringing.
- To avoid degradation of the isolation between the primary and secondary side of the driver, there should not be any trace or conductive area below the driver.
- If the system has multiple layers, it is recommended to connect the VH_x and GNDISO_x pins to internal ground or power planes through multiple vias of adequate size. These vias should be located close to the IC pins to maximize thermal conductivity.

8.2 Layout example

An example of STGAP2HD suggested half-bridge with negative gate driving PCB layout is shown in [Figure 7](#); the main signals have been highlighted by different colors. It is recommended to follow this example for proper positioning and connection of filtering capacitors.
