Functional Description

The CY7C1051DV33 is a high performance CMOS Static RAM organized as 512 K words by 16-bits.

To write to the device, take Chip Enable (\overline{CE}) and Write Enable (\overline{WE}) inputs LOW. If Byte LOW Enable (\overline{BLE}) is LOW, then data from I/O pins (I/O_0 – I/O_7), is written into the location specified on the address pins (A_0 – A_{18}). If Byte HIGH Enable (\overline{BHE}) is LOW, then data from I/O pins (I/O_8 – I/O_{15}) is written into the location specified on the address pins (A_0 – A_{18}).

To read from the device, take Chip Enable (\overline{CE}) and Output Enable (\overline{OE}) LOW while forcing the Write Enable (\overline{WE}) HIGH. If Byte LOW Enable (\overline{BLE}) is LOW, then data from the memory location specified by the address pins appears on I/O_0 – I/O_7 . If Byte HIGH Enable (\overline{BHE}) is LOW, then data from memory appears on I/O_8 to I/O_{15} . See the [Truth Table](#) on page 10 for a complete description of read and write modes.

The input/output pins (I/O_0 – I/O_{15}) are placed in a high-impedance state when the device is deselected (\overline{CE} HIGH), the outputs are disabled (\overline{OE} HIGH), the \overline{BHE} and \overline{BLE} are disabled (\overline{BHE} , \overline{BLE} HIGH), or a write operation (\overline{CE} LOW, and \overline{WE} LOW) is in progress.

The CY7C1051DV33 is available in a 44-pin TSOP II package with center power and ground (revolutionary) pinout and a 48-ball FBGA package.

Notes

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V.
- t_{POWER} gives the minimum amount of time that the power supply must be at typical V_{CC} values until the first memory access can be performed.
- t_{HZOE} , t_{HZCE} , t_{HZBE} and t_{HZWE} are specified with a load capacitance of 5 pF as in part (d) of "AC Test Loads and Waveforms" on page 5. Transition is measured when the outputs enter a high impedance state.
- At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , t_{HZBE} is less than t_{LZBE} , and t_{HZWE} is less than t_{LZWE} for any device.
- The internal write time of the memory is defined by the overlap of \overline{CE} LOW, and \overline{WE} LOW. \overline{CE} and \overline{WE} must be LOW to initiate a write, and the transition of either of these signals can terminate the write. The input data setup and hold timing must refer to the leading edge of the signal that terminates the write.
- The minimum write cycle time for Write Cycle No. 3 (\overline{WE} controlled, \overline{OE} LOW) is the sum of t_{HZWE} and t_{SD} .

Switching Waveforms

Figure 5. Read Cycle No. 2 (\overline{OE} Controlled)^[12, 13]

Notes

- 11. Device is continuously selected. \overline{OE} , $\overline{CE} = V_{IL}$, \overline{BHE} , \overline{BLE} , or both = V_{IL} .
- 12. \overline{WE} is HIGH for Read cycle.
- 13. Address valid before or coincident with \overline{CE} transition LOW.

Figure 7. Write Cycle No. 2 ($\overline{\text{BLE}}$ or $\overline{\text{BHE}}$ Controlled)

Notes

- 14. Data I/O is high-impedance if $\overline{\text{OE}}$, or $\overline{\text{BHE}}$, $\overline{\text{BLE}}$, or both = V_{IH} .
- 15. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ going HIGH, the output remains in a high-impedance state.

Switching Waveforms (continued)
