**Functional Description**

CY7C1061G<sup>[1]</sup> is a high-performance CMOS fast static RAM automotive part with embedded ECC. ECC logic can detect and correct single-bit error in read data word during read cycles.

This device has single chip enable input and is accessed by asserting the chip enable input (CE) LOW.

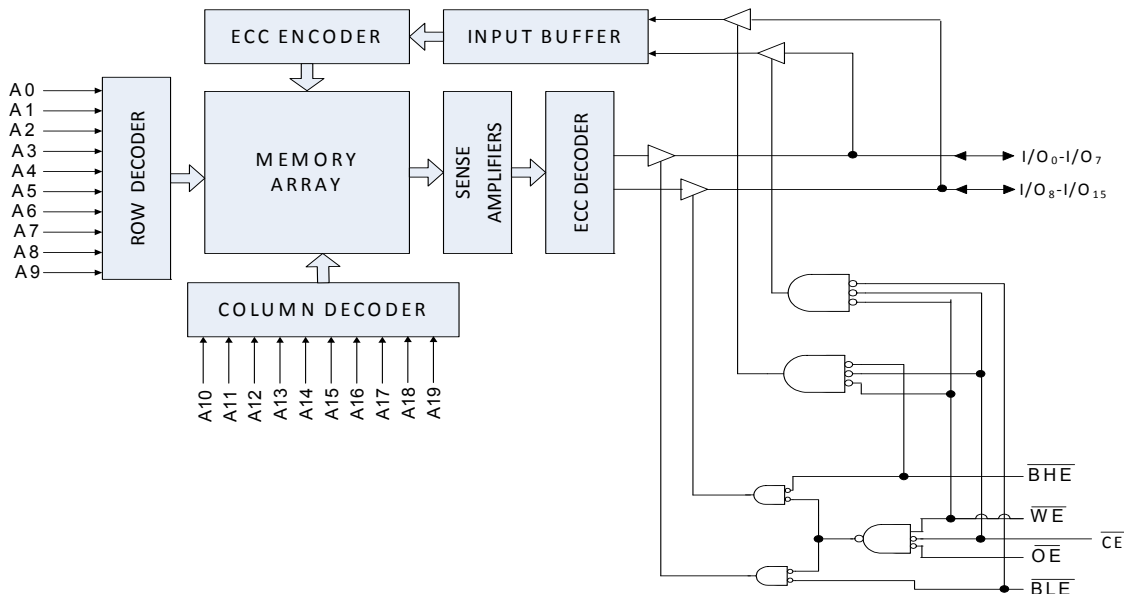

To perform data writes, assert the Write Enable ( $\overline{WE}$ ) input LOW and provide the data and address on the device data pins (I/O<sub>0</sub> through I/O<sub>15</sub>) and address pins (A<sub>0</sub> through A<sub>19</sub>) respectively. The Byte High Enable (BHE) and Byte Low Enable (BLE), inputs control byte writes and write data on the corresponding I/O lines to the memory location specified. BHE controls I/O<sub>8</sub> through I/O<sub>15</sub> and BLE controls I/O<sub>0</sub> through I/O<sub>7</sub>.

To perform data reads, assert the Output Enable ( $\overline{OE}$ ) input and provide the required address on the address lines. Read data is accessible on I/O lines (I/O<sub>0</sub> through I/O<sub>15</sub>). You can perform byte accesses by asserting the required byte enable signal (BHE or BLE) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O<sub>0</sub> through I/O<sub>15</sub>) are placed in a high-impedance state when the device is deselected (CE HIGH), or control signals are de-asserted (OE, BLE, BHE). Refer to the below logic block diagram.

The CY7C1061G automotive device is available in 48-ball VFBGA and 48-pin TSOP I packages.

### Notes

10. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for V<sub>CC</sub> ≥ 3 V) and V<sub>CC</sub>/2 (for V<sub>CC</sub> < 3 V), and input pulse levels of 0 to 3 V (for V<sub>CC</sub> ≥ 3 V) and 0 to V<sub>CC</sub> (for V<sub>CC</sub> < 3V). Test conditions for the read cycle use the output loading shown in part (a) of Figure 3 on page 5, unless specified otherwise.
11. t<sub>POWER</sub> gives the minimum amount of time that the power supply is at stable V<sub>CC</sub> until the first memory access is performed.
12. t<sub>HZOE</sub>, t<sub>HZCE</sub>, t<sub>HZWE</sub>, and t<sub>HZBE</sub> are specified with a load capacitance of 5 pF, as shown in part (b) of Figure 3 on page 5. Hi-Z, Lo-Z transition is measured ±200 mV from steady state voltage.
13. At any temperature and voltage condition, t<sub>HZCE</sub> is less than t<sub>LZCE</sub>, t<sub>HZBE</sub> is less than t<sub>LZBE</sub>, t<sub>HZOE</sub> is less than t<sub>LZOE</sub>, and t<sub>HZWE</sub> is less than t<sub>LZWE</sub> for any device.
14. These parameters are guaranteed by design and are not tested.
15. The internal write time of the memory is defined by the overlap of  $\overline{WE} = V_{IL}$ ,  $\overline{CE} = V_{IL}$  and  $\overline{BHE}$ , or  $\overline{BLE} = V_{IL}$ . These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
16. The minimum write pulse width for Write Cycle No. 2 ( $\overline{WE}$  Controlled,  $\overline{OE}$  LOW) should be sum of t<sub>HZWE</sub> and t<sub>SD</sub>.

These signals must be LOW to initiate a write and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.

- 22. During this period, the I/Os are in output state. Do not apply input signals.
- 23. The minimum write pulse width for Write Cycle No. 2 ( $\overline{\text{WE}}$  Controlled,  $\overline{\text{OE}}$  LOW) should be sum of  $t_{HZWE}$  and  $t_{SD}$ .
