## MCF5301x Data Sheet

### Features

- Version 3 ColdFire® core with EMAC
- Up to 211 Dhrystone 2.1 MIPS @ 240 MHz
- 16 KBytes unified instruction/data cache
- 128 KBytes internal SRAM with standby power supply support
- Crossbar switch technology (XBS) for concurrent access to peripherals or RAM from multiple bus masters
- Enhanced Secure Digital Host Controller (eSDHC)
  - Supports CE-ATA, SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, MMC 4x, and MMC RS cards
- Two ISO7816 smart card interfaces
- IC identification module
- Voice-band audio codec with integrated speaker, microphone, headphone, and handset amplifiers
- 16- or 32-bit SDR, 16-bit DDR/mobile-DDR SDRAM controller
- USB 2.0 On-the-Go controller
- USB host controller
- 2 10/100 Ethernet MACs
- Coprocessor for acceleration of the DES, 3DES, AES, MD5, and SHA-1 algorithms
- Random number generator
- 16-channel DMA controller
- Synchronous serial interface
- 4 periodic interrupt timers
- 4 32-bit timers with DMA support
- Real-time clock (RTC) module with standby support
- DMA-supported serial peripheral interface (DSPI)
- 3 UARTs
- I<sup>2</sup>C bus interface

## 3 Hardware Design Considerations

### 3.1 PLL Power Filtering

To further enhance noise isolation, an external filter is strongly recommended for PLL analog  $V_{DD}$  pins. The filter shown in [Figure 1](#) should be connected between the board  $IV_{DD}$  and the  $PLLV_{DD}$  pins. The resistor and capacitors should be placed as close to the dedicated  $PV_{DD}$  pin as possible. The 10-ohm resistor in the given filter is required, do not implement the filter circuit using only capacitors. The  $PV_{DD}$  pins draw very little current, so concerns regarding voltage loss across the 10-ohm resistor are not valid.

Figure 1. System PLL V<sub>DD</sub> Power Filter

### 3.2 USB Power Filtering

To minimize noise, external filters are required for each of the USB power pins. The filter shown in Figure 2 should be connected between the board EV<sub>DD</sub> and each of the USBV<sub>DD</sub> pins. The resistor and capacitors should be placed as close to the dedicated USBV<sub>DD</sub> pin as possible.

Figure 2. USB V<sub>DD</sub> Power Filter

#### NOTE

In addition to the above filter circuitry, a 0.01 F capacitor is also recommended in parallel with those shown.

### 3.3 Supply Voltage Sequencing

Figure 3 shows situations in sequencing the I/O V<sub>DD</sub> (EV<sub>DD</sub>), SDRAM V<sub>DD</sub> (SDV<sub>DD</sub>), PLL V<sub>DD</sub> (PV<sub>DD</sub>), and internal logic / core V<sub>DD</sub> (IV<sub>DD</sub>). The relationship between SDV<sub>DD</sub> and EV<sub>DD</sub> is non-critical during power-up and power-down sequences. Both SDV<sub>DD</sub> (2.5V or 1.8V) and EV<sub>DD</sub> are specified relative to IV<sub>DD</sub>.

## Notes:

- 1  $IV_{DD}$  should not exceed  $EV_{DD}$ ,  $SDV_{DD}$  or  $PV_{DD}$  by more than 0.4V at any time, including power-up.
- 2 Recommended that  $IV_{DD}/PV_{DD}$  should track  $EV_{DD}/SDV_{DD}$  up to 0.9V then separate for completion of ramps
- 3 Input voltage must not be greater than the supply voltage ( $EV_{DD}$ ,  $SDV_{DD}$ ,  $IV_{DD}$ , or  $PV_{DD}$ ) by more than 0.5V at any time, including during power-up.
- 4 Use 1 microsecond or slower rise time for all supplies.

**Figure 3. Supply Voltage Sequencing and Separation Cautions**

### 3.3.1 Power Up Sequence

If  $EV_{DD}/SDV_{DD}$  are powered up with the  $IV_{DD}$  at 0V, then the sense circuits in the I/O pads will cause all pad output drivers connected to the  $EV_{DD}/SDV_{DD}$  to be in a high impedance state. There is no limit on how long after  $EV_{DD}/SDV_{DD}$  powers up before  $IV_{DD}$  must power up.  $IV_{DD}$  should not lead the  $EV_{DD}$ ,  $SDV_{DD}$  or  $PV_{DD}$  by more than 0.4V during power ramp up or there will be high current in the internal ESD protection diodes. The rise times on the power supplies should be slower than 1 microsecond to avoid turning on the internal ESD protection clamp diodes.

The recommended power up sequence is as follows:

1. Use 1 microsecond or slower rise time for all supplies.
2.  $IV_{DD}/PV_{DD}$  and  $EV_{DD}/SDV_{DD}$  should track up to 0.9V and then separate for the completion of ramps with  $EV_{DD}/SDV_{DD}$  going to the higher external voltages. One way to accomplish this is to use a low drop-out voltage regulator.

### 3.3.2 Power Down Sequence

If  $IV_{DD}/PV_{DD}$  are powered down first, then sense circuits in the I/O pads will cause all output drivers to be in a high impedance state. There is no limit on how long after  $IV_{DD}$  and  $PV_{DD}$  power down before  $EV_{DD}$  or  $SDV_{DD}$  must power down.  $IV_{DD}$  should not lag  $EV_{DD}$ ,  $SDV_{DD}$ , or  $PV_{DD}$  going low by more than 0.4V during power down or there will be undesired high current in the ESD protection diodes. There are no requirements for the fall times of the power supplies.

The recommended power down sequence is as follows:

1. Drop  $IV_{DD}/PV_{DD}$  to 0V.
2. Drop  $EV_{DD}/SDV_{DD}$  supplies.

### 3.4 Power Consumption Specifications

Estimated maximum RUN mode power consumption measurements are shown in the below figure.

## 4 Pin Assignments and Reset States

### 4.1 Signal Multiplexing

The following table lists all the MCF5301x pins grouped by function. The “Dir” column is the direction for the primary function of the pin only. Refer to [Section 4.2, “Pinout—208 LQFP,”](#) and [Section 4.3, “Pinout—256 MAPBGA,”](#) for package diagrams. For a more detailed discussion of the MCF3xxx signals, consult the *MCF5301x Reference Manual (MCF53017RM)*.

#### NOTE

In this table and throughout this document a single signal within a group is designated without square brackets (i.e., FB\_A23), while designations for multiple signals within a group use brackets (i.e., FB\_A[23:21]) and is meant to include all signals within the two bracketed numbers when these numbers are separated by a colon.

#### NOTE

The primary functionality of a pin is not necessarily its default functionality. Most pins that are muxed with GPIO will default to their GPIO functionality. See [Table 5](#) for a list of the exceptions.

<sup>1</sup> Pull-ups are generally only enabled on pins with their primary function, except as noted.

<sup>2</sup> Refers to pin's primary function.

<sup>3</sup> Enabled only in oscillator bypass mode (internal crystal oscillator is disabled).

<sup>4</sup> The edge port 1 signals are the primary functions on two sets of pins (IRQ1FEC $n$  and IRQ1DEBUG $n$ ). If an IRQ1 function is configured on both pins, the IRQ1FEC $n$  pin takes priority. The corresponding IRQ1DEBUG $n$  pin is disconnected internally from the edge port 1 module.

<sup>5</sup> GPIO functionality is determined by the edge port module. The GPIO module is only responsible for assigning the alternate functions.

<sup>6</sup> If JTAG\_EN is asserted, these pins default to alternate 1 (JTAG) functionality. The GPIO module is not responsible for assigning these pins.

## 5 Preliminary Electrical Characteristics

This document contains electrical specification tables and reference timing diagrams for the MCF5301x microprocessor. This section contains detailed information on DC/AC electrical characteristics and AC timing specifications.

The electrical specifications are preliminary and are from previous designs or design simulations. These specifications may not be fully tested or guaranteed at this early stage of the product life cycle, however for production silicon these specifications will be met. Finalized specifications will be published after complete characterization and device qualifications have been completed.

### NOTE

The parameters specified in this MCU document supersede any values found in the module specifications.

### 5.1 Maximum Ratings

Table 7. Absolute Maximum Ratings<sup>1, 2</sup>

Rating	Symbol	Value	Unit
Core Supply Voltage	$IV_{DD}$	-0.5 to +2.0	V
CMOS Pad Supply Voltage	$EV_{DD}$	-0.3 to +4.0	V
DDR/Memory Pad Supply Voltage	$SDV_{DD}$	-0.3 to +4.0	V
PLL Supply Voltage	$PLLV_{DD}$	-0.3 to +2.0	V
Digital Input Voltage <sup>3</sup>	$V_{IN}$	-0.3 to +3.6	V
Instantaneous Maximum Current Single pin limit (applies to all pins) <sup>3, 4, 5</sup>	$I_D$	25	mA
Operating Temperature Range (Packaged)	$T_A$ ( $T_L - T_H$ )	-40 to +85	°C
Storage Temperature Range	$T_{stg}$	-55 to +150	°C

<sup>1</sup> Functional operating conditions are given in Section 5.4, "DC Electrical Specifications." Absolute maximum ratings are stress ratings only, and functional operation at the maxima is not guaranteed. Continued operation at these levels may affect device reliability or cause permanent damage to the device.

<sup>2</sup> This device contains circuitry protecting against damage due to high static voltage or electrical fields; however, it is advised that normal precautions be taken to avoid application of any voltages higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are tied to an appropriate logic voltage level (e.g., either  $V_{SS}$  or  $EV_{DD}$ ).

<sup>3</sup> Input must be current limited to the value specified. To determine the value of the required current-limiting resistor, calculate resistance values for positive and negative clamp voltages, then use the larger of the two values.

<sup>4</sup> All functional non-supply pins are internally clamped to  $V_{SS}$  and  $EV_{DD}$ .

<sup>5</sup> Power supply must maintain regulation within operating  $EV_{DD}$  range during instantaneous and operating maximum current conditions. If positive injection current ( $V_{in} > EV_{DD}$ ) is greater than  $I_{DD}$ , the injection current may flow out of  $EV_{DD}$  and could result in external power supply going out of regulation. Insure external  $EV_{DD}$  load will shunt current greater than maximum injection current. This will be the greatest risk when the MCU is not consuming power (ex; no clock). Power supply must maintain regulation within operating  $EV_{DD}$  range during instantaneous and operating maximum current conditions.

## 5.2 Thermal Characteristics

Table 8. Thermal Characteristics

Characteristic		Symbol	256 MABGA	208 LQFP	Unit
Junction to ambient, natural convection	Four layer board (2s2p)	$\theta_{JMA}$	36 <sup>1,2</sup>	38 <sup>1,2</sup>	°C/W
Junction to ambient (@200 ft/min)	Four layer board (2s2p)	$\theta_{JMA}$	32 <sup>1,2</sup>	33 <sup>1,2</sup>	°C/W
Junction to board		$\theta_{JB}$	25 <sup>3</sup>	29 <sup>3</sup>	°C/W
Junction to case		$\theta_{JC}$	14 <sup>4</sup>	11 <sup>4</sup>	°C/W
Junction to top of package		$\Psi_{jt}$	2 <sup>1,5</sup>	3 <sup>1,5</sup>	°C/W
Maximum operating junction temperature		$T_j$	105	105	°C

<sup>1</sup>  $\theta_{JMA}$  and  $\Psi_{jt}$  parameters are simulated in conformance with EIA/JESD Standard 51-2 for natural convection. Freescale recommends the use of  $\theta_{JMA}$  and power dissipation specifications in the system design to prevent device junction temperatures from exceeding the rated specification. System designers should be aware that device junction temperatures can be significantly influenced by board layout and surrounding devices. Conformance to the device junction temperature specification can be verified by physical measurement in the customer's system using the  $\Psi_{jt}$  parameter, the device power dissipation, and the method described in EIA/JESD Standard 51-2.

<sup>2</sup> Per JEDEC JESD51-6 with the board horizontal.

<sup>3</sup> Thermal resistance between the die and the printed circuit board in conformance with JEDEC JESD51-8. Board temperature is measured on the top surface of the board near the package.

<sup>4</sup> Thermal resistance between the die and the case top surface as measured by the cold plate method (MIL SPEC-883 Method 1012.1).

<sup>5</sup> Thermal characterization parameter indicating the temperature difference between package top and the junction temperature per JEDEC JESD51-2. When Greek letters are not available, the thermal characterization parameter is written in conformance with Psi-JT.

The average chip-junction temperature ( $T_j$ ) in °C can be obtained from:

$$T_j = T_A + (P_D \times \theta_{JMA}) \quad \text{Eqn. 1}$$

Where:

$T_A$	= Ambient Temperature, °C
$\theta_{JMA}$	= Package Thermal Resistance, Junction-to-Ambient, °C/W
$P_D$	= $P_{INT} + P_{I/O}$
$P_{INT}$	= $I_{DD} \times IV_{DD}$ , Watts - Chip Internal Power
$P_{I/O}$	= Power Dissipation on Input and Output Pins - User Determined

For most applications  $P_{I/O} < P_{INT}$  and can be ignored. An approximate relationship between  $P_D$  and  $T_j$  (if  $P_{I/O}$  is neglected) is:

$$P_D = \frac{K}{(T_j + 273^\circ C)} \quad \text{Eqn. 2}$$

Solving equations 1 and 2 for K gives:

$$K = P_D \times (T_A \times 273^\circ C) + \theta_{JMA} \times P_D^2 \quad \text{Eqn. 3}$$

where  $K$  is a constant pertaining to the particular part.  $K$  can be determined from Equation 3 by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of  $K$ , the values of  $P_D$  and  $T_J$  can be obtained by solving Equation 1 and Equation 2 iteratively for any value of  $T_A$ .

### 5.3 ESD Protection

Table 9. ESD Protection Characteristics<sup>1, 2</sup>

Characteristics	Symbol	Value	Units
ESD Target for Human Body Model	HBM	2000	V

<sup>1</sup> All ESD testing is in conformity with JEDEC JESD22-A114 specification.

<sup>2</sup> A device is defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing is performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

### 5.4.1 PLL Power Filtering

To further enhance noise isolation, an external filter is strongly recommended for PLL analog  $V_{DD}$  pins. The filter shown in Figure 8 should be connected between the board  $V_{DD}$  and the  $PLL V_{DD}$  pins. The resistor and capacitors should be placed as close to the dedicated  $PLL V_{DD}$  pin as possible.

Figure 8. System PLL  $V_{DD}$  Power Filter

### 5.4.2 USB Power Filtering

To minimize noise, external filters are required for each of the USB power pins. The filter shown in Figure 2 should be connected between the board  $EV_{DD}$  or  $IV_{DD}$  and each of the  $USBV_{DD}$  pins. The resistor and capacitors should be placed as close to the dedicated  $USBV_{DD}$  pin as possible.

Figure 9. USB  $V_{DD}$  Power Filter

#### NOTE

In addition to the above filter circuitry, a 0.01 F capacitor is also recommended in parallel with those shown.

### 5.4.3 Supply Voltage Sequencing and Separation Cautions

The relationship between  $SDV_{DD}$  and  $EV_{DD}$  is non-critical during power-up and power-down sequences. Both  $SDV_{DD}$  (2.5V or 3.3V) and  $EV_{DD}$  are specified relative to  $IV_{DD}$ .

#### 5.4.3.1 Power Up Sequence

If  $EV_{DD}/SDV_{DD}$  are powered up with  $IV_{DD}$  at 0 V, then the sense circuits in the I/O pads will cause all pad output drivers connected to the  $EV_{DD}/SDV_{DD}$  to be in a high impedance state. There is no limit on how long after  $EV_{DD}/SDV_{DD}$  powers up before  $IV_{DD}$  must be powered up.  $IV_{DD}$  should not lead the  $EV_{DD}$ ,  $SDV_{DD}$  or  $PLL_{DD}$  by more than 0.4 V during power ramp-up, or there will be high current in the internal ESD protection diodes. The rise times on the power supplies should be slower than 500  $\mu$ s to avoid turning on the internal ESD protection clamp diodes.

#### 5.4.3.2 Power Down Sequence

If  $IV_{DD}/PLL_{DD}$  are powered down first, then sense circuits in the I/O pads will cause all output drivers to be in a high impedance state. There is no limit on how long after  $IV_{DD}$  and  $PLL_{DD}$  power down before  $EV_{DD}$  or  $SDV_{DD}$  must power down.  $IV_{DD}$  should not lag  $EV_{DD}$ ,  $SDV_{DD}$ , or  $PLL_{DD}$  going low by more than 0.4 V during power down or there will be undesired high current in the ESD protection diodes. There are no requirements for the fall times of the power supplies.

The recommended power down sequence is as follows:

1. Drop  $IV_{DD}/PLL_{DD}$  to 0 V.
2. Drop  $EV_{DD}/SDV_{DD}$  supplies.

19	VCO Frequency. $f_{VCO} = (f_{ref} \times PFD)/4$	$f_{VCO}$	200	667	MHz

<sup>1</sup> The maximum allowable input clock frequency when booting with the PLL enabled is 24MHz. For higher input clock frequencies the processor must boot in LIMP mode to avoid violating the maximum allowable CPU frequency.

<sup>2</sup> All internal registers retain data at 0 Hz.

<sup>3</sup> This parameter is guaranteed by characterization before qualification rather than 100% tested.

<sup>4</sup> Proper PC board layout procedures must be followed to achieve specifications.

<sup>5</sup> This parameter is guaranteed by design rather than 100% tested.

<sup>6</sup> This specification is the PLL lock time only and does not include oscillator start-up time..

<sup>7</sup>  $C_{PCB\_EXTAL}$  and  $C_{PCB\_XTAL}$  are the measured PCB stray capacitances on EXTAL and XTAL, respectively.

- <sup>8</sup> Jitter is the average deviation from the programmed frequency measured over the specified interval at maximum  $f_{SYS}$ . Measurements are made with the device powered by filtered supplies and clocked by a stable external clock signal. Noise injected into the PLL circuitry via PLL  $V_{DD}$ ,  $EV_{DD}$ , and  $V_{SS}$  and variation in crystal oscillator frequency increase the  $C_{jitter}$  percentage for a given interval.
- <sup>9</sup> Values are with frequency modulation disabled. If frequency modulation is enabled, jitter is the sum of  $C_{jitter} + C_{mod}$ .
- <sup>10</sup> Modulation percentage applies over an interval of  $10\mu s$ , or equivalently the modulation rate is 100kHz.
- <sup>11</sup> Modulation range determined by hardware design.

## 5.6 External Interface Timing Characteristics

Table 12 lists processor bus input timings.

### NOTE

All processor bus timings are synchronous; that is, input setup/hold and output delay with respect to the rising edge of a reference clock. The reference clock is the FB\_CLK output.

All other timing relationships can be derived from these values. Timings listed in Table 12 are shown in Figure 11 and Figure 12.

\* The timings are also valid for inputs sampled on the negative clock edge.

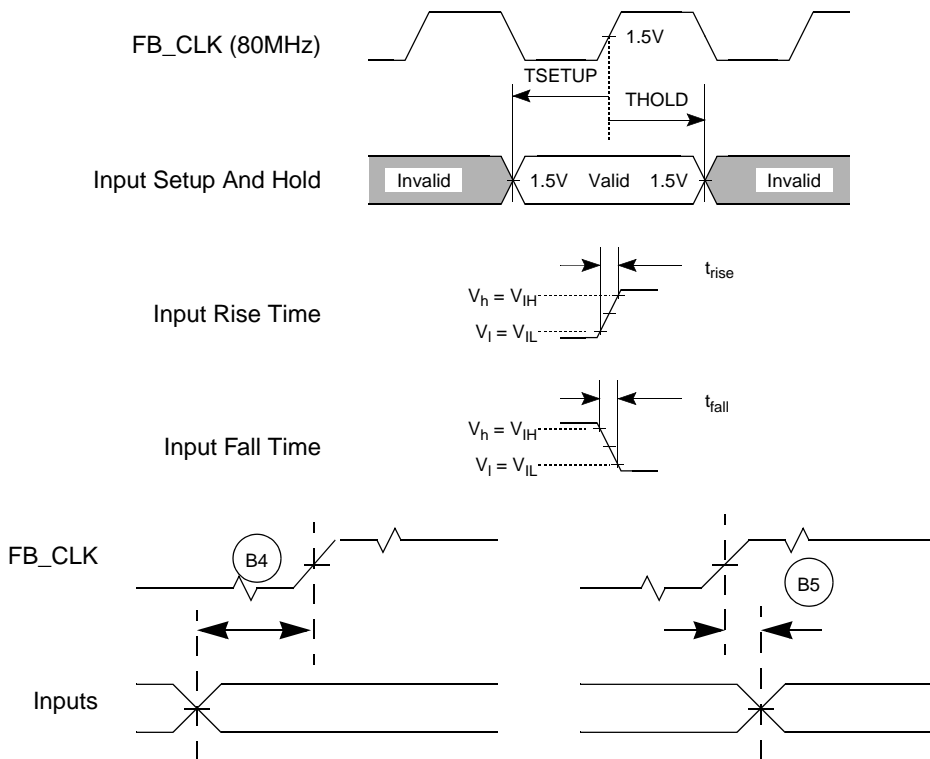

Figure 10. General Input Timing Requirements

### 5.6.1 FlexBus

A multi-function external bus interface called FlexBus is provided with basic functionality to interface to slave-only devices up to a maximum bus frequency of 80MHz. It can be directly connected to asynchronous or synchronous devices such as external boot ROMs, flash memories, gate-array logic, or other simple target (slave) devices with little or no additional circuitry. For asynchronous devices a simple chip-select based interface can be used. The FlexBus interface has six general purpose chip-selects ( $\overline{FB\_CS}[5:0]$ ) which can be configured to be distributed between the FlexBus or SDRAM memory interfaces.

## Preliminary Electrical Characteristics

Chip-select,  $\overline{\text{FB\_CS0}}$  can be dedicated to boot ROM access and can be programmed to be byte (8 bits), word (16 bits), or longword (32 bits) wide. Control signal timing is 1\*compatible with common ROM/flash memories.

### 5.6.1.1 FlexBus AC Timing Characteristics

The following timing numbers indicate when data will be latched or driven onto the external bus, relative to the system clock.

**Table 12. FlexBus AC Timing Specifications**

Num	Characteristic	Symbol	Min	Max	Unit	Notes
	Frequency of Operation		—	80	Mhz	$f_{\text{sys}/3}$

FB7	Transfer Acknowledge ( $\overline{\text{TA}}$ ) Input Hold	$t_{\text{CIFBCH}}$	0	—	ns	

<sup>1</sup> Timing for chip selects only applies to the  $\overline{\text{FB\_CS}}[5:0]$  signals. Please see [Section 5.7.2, “DDR SDRAM AC Timing Characteristics”](#) for  $\overline{\text{SD\_CS}}[3:0]$  timing.

<sup>2</sup> The FlexBus supports programming an extension of the address hold. Please consult the *MCF5301x Reference Manual* for more information.

#### NOTE

The processor drives the data lines during the first clock cycle of the transfer with the full 32-bit address. This may be ignored by standard connected devices using non-multiplexed address and data buses. However, some applications may find this feature beneficial.

The address and data busses are muxed between the FlexBus and SDRAM controller. At the end of the read and write bus cycles the address signals are indeterminate.

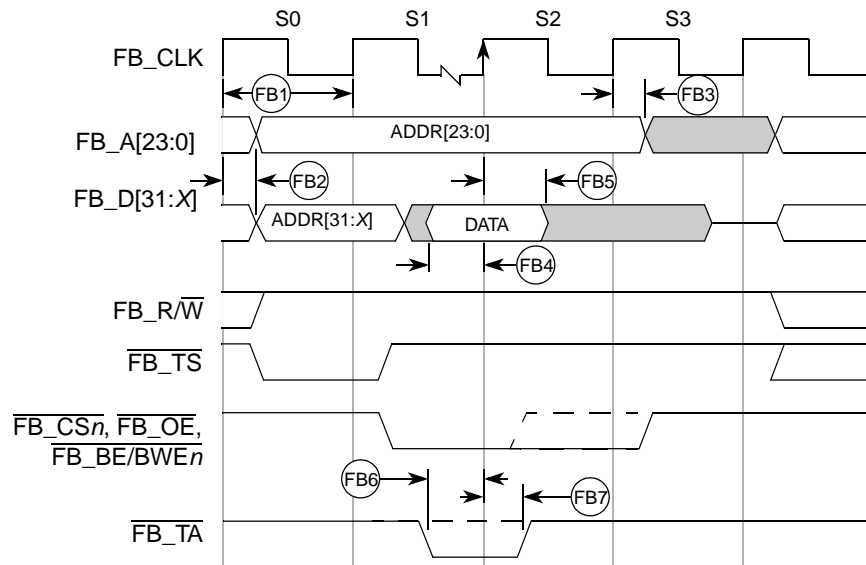

Figure 11. FlexBus Read Timing

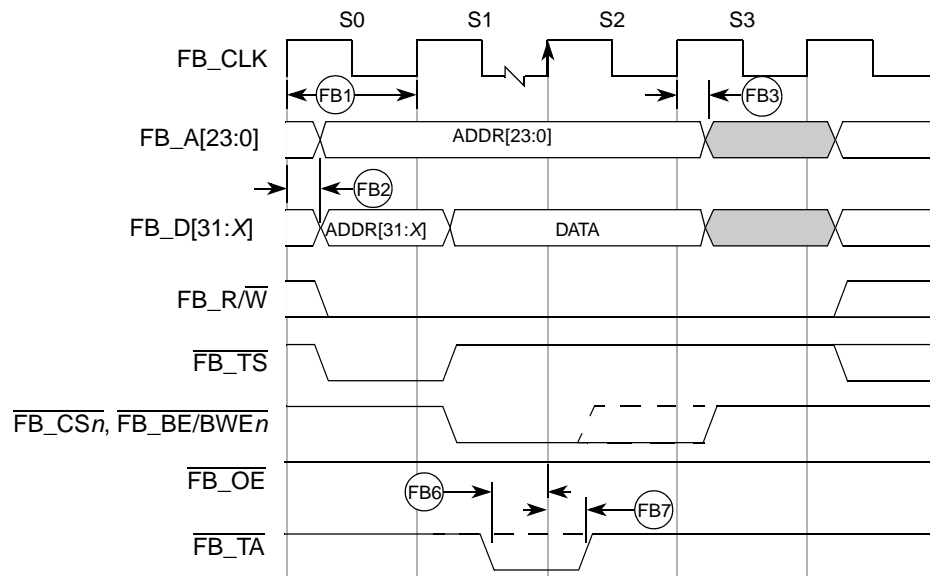

Figure 12. Flexbus Write Timing

## 5.7 SDRAM Bus

The SDRAM controller supports accesses to main SDRAM memory from any internal master. It supports either standard SDRAM or double data rate (DDR) SDRAM, but it does not support both at the same time.

### 5.7.1 SDR SDRAM AC Timing Characteristics

The following timing numbers indicate when data will be latched or driven onto the external bus, relative to the memory bus clock, when operating in SDR mode on write cycles and relative to SD\_DQS on read cycles. The device's SDRAM controller is a DDR controller that has an SDR mode. Because it is designed to support DDR, a DQS pulse must still be supplied to the device for each data beat of an SDR read. The processor accomplishes this by asserting a signal named SD\_SDR\_DQS during

## Preliminary Electrical Characteristics

read cycles. Care must be taken during board design to adhere to the following guidelines and specs with regard to the SD\_SDR\_DQS signal and its usage.

**Table 13. SDR Timing Specifications**

Symbol	Characteristic	Symbol	Min	Max	Unit	Notes
	Frequency of operation		50	80	Mhz	1
SD1	Clock period	$t_{SDCK}$	12.5	20	ns	2
SD2	Pulse width high	$t_{SDCKH}$	0.45	0.55	SD_CLK	3

SD9	Data (D[31:0]) input setup relative to SD_CLK (reference only)	$t_{DVSDCH}$	$0.25 \times SD\_CLK$	—	ns	8
SD10	Data input hold relative to SD_CLK (reference only)	$t_{DISDCH}$	1.0	—	ns	
SD11	Data (D[31:0]) and data mask (SD_DQM[3:0]) output valid	$t_{SDCHDMV}$	—	$0.75 \times SD\_CLK + 0.5$	ns	
SD12	Data (D[31:0]) and data mask (SD_DQM[3:0]) output hold	$t_{SDCHDMI}$	1.5	—	ns	

<sup>1</sup> The device supports same frequency of operation for both FlexBus and SDRAM clock operates as that of the internal bus clock. Please see the PLL chapter of the *MCF5301x Reference Manual* for more information on setting the SDRAM clock rate.

<sup>2</sup> SD\_CLK is one SDRAM clock in (ns).

<sup>3</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.

<sup>4</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.

<sup>5</sup> SD\_DQS is designed to pulse 0.25 clock before the rising edge of the memory clock. This is a guideline only. Subtle variation from this guideline is expected. SD\_DQS will only pulse during a read cycle and one pulse will occur for each data beat.

<sup>6</sup> SDR\_DQS is designed to pulse 0.25 clock before the rising edge of the memory clock. This spec is a guideline only. Subtle variation from this guideline is expected. SDR\_DQS will only pulse during a read cycle and one pulse will occur for each data beat.

<sup>7</sup> The SDR\_DQS pulse is designed to be 0.5 clock in width. The timing of the rising edge is most important. The falling edge does not affect the memory controller.

<sup>8</sup> Since a read cycle in SDR mode still uses the DQS circuit within the device, it is most critical that the data valid window be centered 1/4 clk after the rising edge of DQS. Ensuring that this happens will result in successful SDR reads. The input setup spec is just provided as guidance.

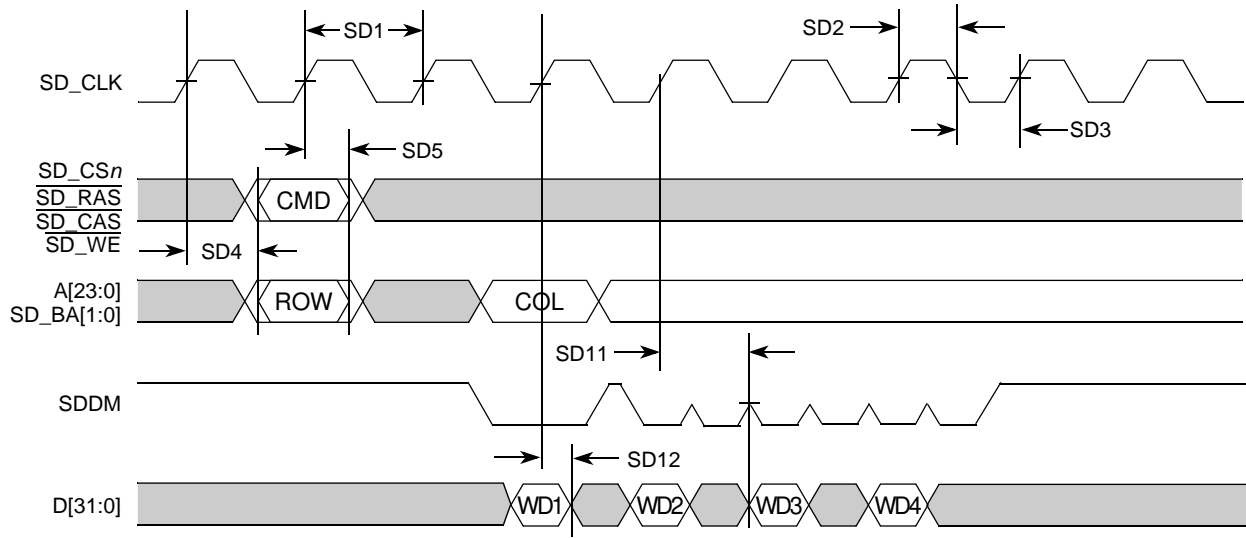

Figure 13. SDR Write Timing

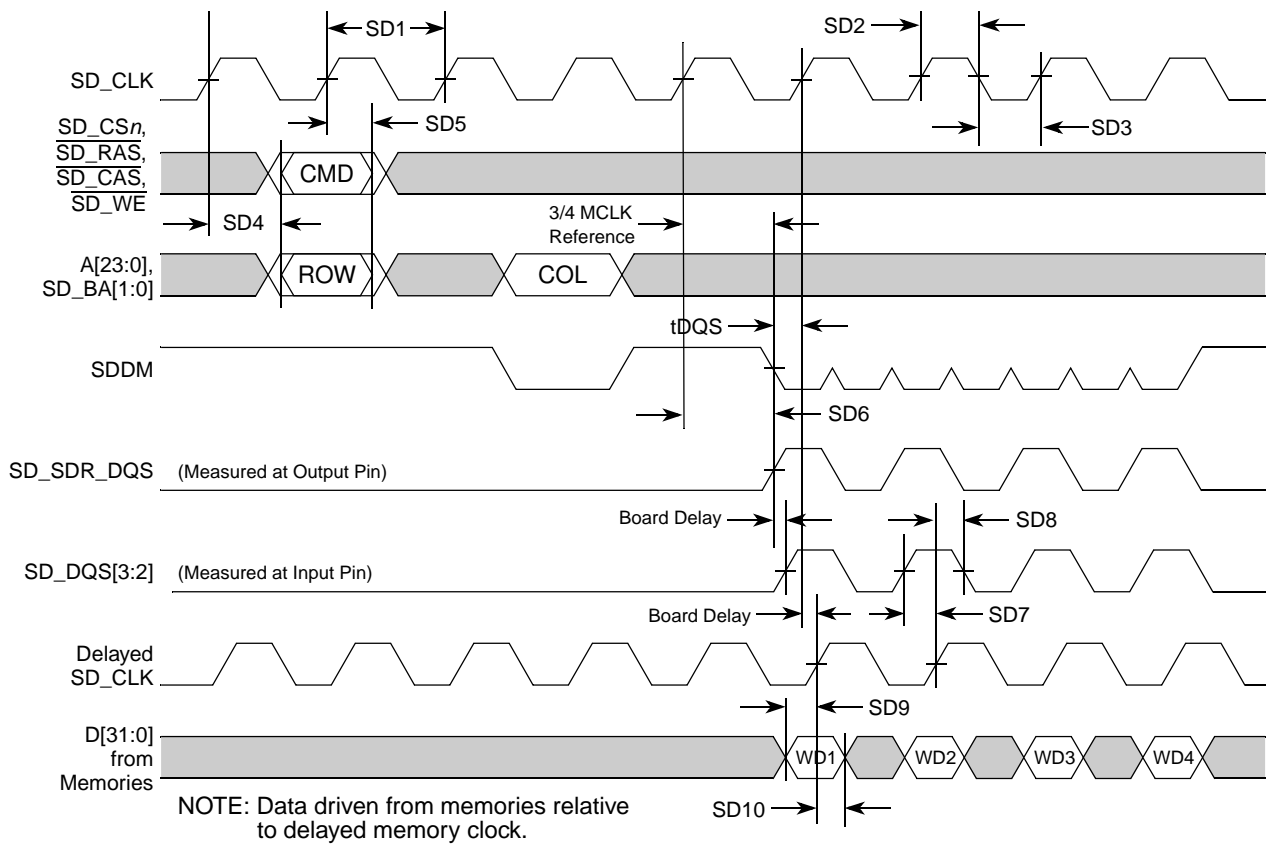

Figure 14. SDR Read Timing

## 5.7.2 DDR SDRAM AC Timing Characteristics

When the SDRAM controller is configured for DDR SDRAM, the following timing numbers must be followed to properly latch or drive data onto the memory bus. All timing numbers are relative to the four DQS byte lanes. The following timing numbers are subject to change at anytime, and are only provided to aid in early board design.

**Table 14. DDR Timing Specifications**

Num	Characteristic	Symbol	Min	Max	Unit	Notes
	Frequency of Operation	$t_{DDCK}$	50	80	Mhz	1
DD1	Clock Period	$t_{DDSK}$	12.5	20	ns	2
DD2	Pulse Width High	$t_{DDCKH}$	0.45	0.55	SD_CLK	3

DD8	Data and Data Mask Output Hold (DQS-->DQ) Relative to DQS (DDR Write Mode)	$t_{DQDMI}$	1.0	—	ns	7
DD9	Input Data Skew Relative to DQS (Input Setup)	$t_{DQDQ}$	—	1	ns	8
DD10	Input Data Hold Relative to DQS.	$t_{DQDQ}$	$0.25 \times SD\_CLK + 0.5ns$	—	ns	9
DD11	DQS falling edge from SDCLK rising (output hold time)	$t_{DQLSDCH}$	0.5	—	ns	
DD12	DQS input read preamble width	$t_{DQRPRE}$	0.9	1.1	SD_CLK	
DD13	DQS input read postamble width	$t_{DQRPST}$	0.4	0.6	SD_CLK	
DD14	DQS output write preamble width	$t_{DQWPRE}$	0.25	—	SD_CLK	
DD15	DQS output write postamble width	$t_{DQWPST}$	0.4	0.6	SD_CLK	

<sup>1</sup> The frequency of operation is either 2x or 4x the FB\_CLK frequency of operation. FlexBus and SDRAM clock operate at the same frequency as the internal bus clock.

<sup>2</sup> SD\_CLK is one SDRAM clock in (ns).

<sup>3</sup> Pulse width high plus pulse width low cannot exceed min and max clock period.

<sup>4</sup> Command output valid should be 1/2 the memory bus clock (SD\_CLK) plus some minor adjustments for process, temperature, and voltage variations.

<sup>5</sup> This specification relates to the required input setup time of today's DDR memories. The device's output setup should be larger than the input setup of the DDR memories. If it is not larger, then the input setup on the memory will be in violation. SD\_D[31:24] is relative to SD\_DQS3, SD\_D[23:16] is relative to SD\_DQS2, SD\_D[15:8] is relative to SD\_DQS1, and SD\_D[7:0] is relative SD\_DQS0.

<sup>6</sup> The first data beat will be valid before the first rising edge of DQS and after the DQS write preamble. The remaining data beats will be valid for each subsequent DQS edge.

<sup>7</sup> This specification relates to the required hold time of today's DDR memories. SD\_D[31:24] is relative to SD\_DQS3, SD\_D[23:16] is relative to SD\_DQS2, SD\_D[15:8] is relative to SD\_DQS1, and SD\_D[7:0] is relative SD\_DQS0.

- <sup>8</sup> Data input skew is derived from each DQS clock edge. It begins with a DQS transition and ends when the last data line becomes valid. This input skew must include DDR memory output skew and system level board skew (due to routing or other factors).
- <sup>9</sup> Data input hold is derived from each DQS clock edge. It begins with a DQS transition and ends when the first data line becomes invalid.

## 5.11 SSI Timing Specifications

This section provides the AC timings for the SSI in master (clocks driven) and slave modes (clocks input). All timings are given for non-inverted serial clock polarity (SSI\_TCR[TSCKP] = 0, SSI\_RCR[RSCKP] = 0) and a non-inverted frame sync (SSI\_TCR[TFSI] = 0, SSI\_RCR[RFSI] = 0). If the polarity of the clock and/or the frame sync have been inverted, all the timings remain valid by inverting the clock signal (SSI\_BCLK) and/or the frame sync (SSI\_FS) shown in the figures below.

**Table 17. SSI Timing - Master Modes<sup>1</sup>**

Num	Description	Symbol	Min	Max	Units	Notes
S1	SSI_MCLK cycle time	$t_{MCLK}$	$8 \times t_{SYS}$	—	ns	<sup>2</sup>
S2	SSI_MCLK pulse width high / low		45%	55%	$t_{MCLK}$

S9	SSI_RXD / SSI_FS input setup before SSI_BCLK		10	—	ns	
S10	SSI_RXD / SSI_FS input hold after SSI_BCLK		0	—	ns	

<sup>1</sup> All timings specified with a capacitive load of 25pF.

<sup>2</sup> SSI\_MCLK can be generated from SSI\_CLKIN or a divided version of the internal system clock (SYSCLK).

<sup>3</sup> SSI\_BCLK can be derived from SSI\_CLKIN or a divided version of SYSCLK. If the SYSCLK is used, the minimum divider is 6. If the SSI\_CLKIN input is used, the programmable dividers must be set to ensure that SSI\_BCLK does not exceed  $4 \times f_{SYS}$ .

I6 <sup>1</sup>	Clock high time	10	—	$t_{cyc}$
I7 <sup>1</sup>	Data setup time	2	—	$t_{cyc}$
I8 <sup>1</sup>	Start condition setup time (for repeated start condition only)	20	—	$t_{cyc}$
I9 <sup>1</sup>	Stop condition setup time	10	—	$t_{cyc}$

<sup>1</sup> Output numbers depend on the value programmed into the IFDR; an IFDR programmed with the maximum frequency (IFDR = 0x20) results in minimum output timings as shown in Table 20. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the SCL low period. The actual position is affected by the prescale and division values programmed into the IFDR; however, the numbers given in Table 20 are minimum values.

<sup>2</sup> Because I2C\_SCL and I2C\_SDA are open-collector-type outputs, which the processor can only actively drive low, the time I2C\_SCL or I2C\_SDA take to reach a high level depends on external signal capacitance and pull-up resistor values.

<sup>3</sup> Specified at a nominal 50-pF load.

Figure 22 shows timing for the values in Table 20 and Table 19.

### 5.15 DSPI Timing Specifications

The DMA Serial Peripheral Interface (DSPI) provides a synchronous serial bus with both master and slave operations. Many of the transfer attributes are programmable. Table 26 provides DSPI timing characteristics for classic SPI timing modes. Refer to the DSPI chapter of the *MCF5301x Reference Manual* for information on the modified transfer formats used for communicating with slower peripheral devices.

<sup>1</sup> Timings shown are for DMCR[MTFE] = 0 (classic SPI) and DCTAR<sub>n</sub>[CPHA] = 0. Data is sampled on the DSPI\_SIN pin on the odd-numbered DSPI\_SCK edges and driven on the DSPI\_SOUT pin on even-numbered DSPI edges.

<sup>2</sup> When in master mode, the baud rate is programmable in DCTAR<sub>n</sub>[DBR], DCTAR<sub>n</sub>[PBR], and DCTAR<sub>n</sub>[BR].

<sup>3</sup> This specification assumes a 50/50 duty cycle setting. The duty cycle is programmable in DCTAR<sub>n</sub>[DBR], DCTAR<sub>n</sub>[CPHA], and DCTAR<sub>n</sub>[PBR].

<sup>4</sup> The DSPI\_PCS<sub>n</sub> to DSPI\_SCK delay is programmable in DCTAR<sub>n</sub>[PCSSCK] and DCTAR<sub>n</sub>[CSSCK].

<sup>5</sup> The DSPI\_SCK to DSPI\_PCS<sub>n</sub> delay is programmable in DCTAR<sub>n</sub>[PASC] and DCTAR<sub>n</sub>[ASC].

## 5.17 SIM Electrical Specifications

Each SIM card interface consist of a total of 12 pins (two separate ports of six pins each. Mostly one port with 5 pins is used). The interface is meant to be used with synchronous SIM cards. This means that the SIM module provides a clock for the SIM card to use. The frequency of this clock is normally 372 times the data rate on the TX/RX pins, however SIM module can work with CLK equal to 16 times the data rate on TX/RX pins.

There is no timing relationship between the clock and the data. The clock that the SIM module provides to the SIM card is used by the SIM card to recover the clock from the data, like a standard UART. All six (or five when a bidirectional TXRX is used) of the pins for each half of the SIM module are asynchronous to each other. There are no required timing relationships between the signals in normal mode. However, there are some in reset and power down sequences.

### 5.17.1 General Timing Requirements

Figure 30 shows the timing of the SIM module, and Table 29 lists the timing parameters.

## 5.17.2 Reset Sequence

### 5.17.2.1 Cards with Internal Reset

The reset sequence for this kind of SIM card is as follows (see Figure 31):

- After powerup, the clock signal is enabled on SIM\_CLK (time T0)
- After 200 clock cycles, RX must be high.
- The card must send a response on RX acknowledging the reset between 400 and 40,000 clock cycles after T0.

**Figure 31. Internal-Reset Card Reset Sequence**

### 5.17.2.2 Cards with Active-Low Reset

The sequence of reset for this kind of card is as follows (see Figure 32):

1. After powerup, the clock signal is enabled on SIM\_CLK (time T0)
2. After 200 clock cycles, RX must be high.
3. SIM\_RST must remain low for at least 40,000 clock cycles after T0 (no response is to be received on RX during those 40,000 clock cycles)
4. SIM\_RST is set high (time T1)
5. SIM\_RST must remain high for at least 40,000 clock cycles after T1 and a response must be received on RX between 400 and 40,000 clock cycles after T1.

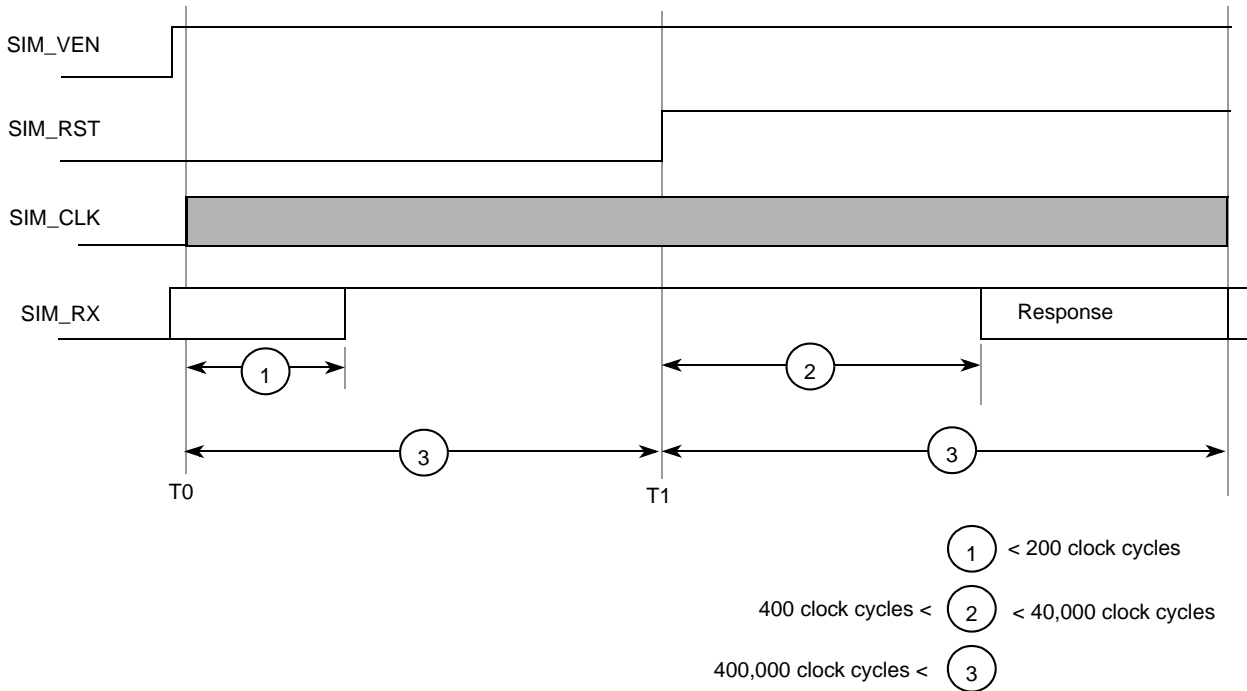

Figure 32. Active-Low-Reset Card Reset Sequence

### 5.17.3 Power Down Sequence

Power down sequence for SIM interface is as follows:

1. SIM\_PD port detects the removal of the SIM card
2. SIM\_RST goes low
3. SIM\_CLK goes low
4. SIM\_TX goes low
5. SIM\_VEN goes low

Each of these steps is completed in one CKIL period (usually 32 kHz). Power-down may be started in response to a card-removal detection or launched by the processor. Figure 33 and Table 30 show the usual timing requirements for this sequence, with  $F_{ckil} = CKIL$  frequency value.

Table 30. Timing Requirements for Power Down Sequence

Num	Description	Symbol	Min	Max	Unit
1	SIM reset to SIM clock stop	$S_{rst2clk}$	$0.9 \div f_{CKIL}$	0.8	$\mu s$
2	SIM reset to SIM TX data low	$S_{rst2dat}$	$1.8 \div f_{CKIL}$	1.2	$\mu s$
3	SIM reset to SIM Voltage Enable Low	$S_{rst2ven}$	$2.7 \div f_{CKIL}$	1.8	$\mu s$

<sup>1</sup> The program length is defined by the value defined in IIM\_FCR[PRG\_LENGTH] of the IIM module. The value to program is based on a 32 kHz clock source ( $4 \div 32 \text{ kHz} = 125 \mu\text{s}$ )

## 5.19 Voice Codec

The voice codec function is analog-to-digital and digital-to-analog conversion of the voice signal. The following section contains detailed electrical specifications for the analog and digital parts' performance. The voice codec is powered down when not enabled for power consumption.

Table 32 shows the voice codec general specifications.

### 5.19.1 Voice Codec ADC Specifications

Voice coding function includes a 50 kHz second-order, low-pass anti-aliasing filter, an analog-to-digital converter, digital filters for decimation, band-passing, frequency ripple compensation, and DSP interface logic. The audio input A/D converter converts the incoming signal to 13-bit two's-complement linear PCM words at an 8 or 8.1 kHz rate. Following the A/D converter, the signal is digitally filtered, low-pass, and selectable high-pass. Table 33 shows the voice coding specifications.

<sup>1</sup> All analog signals are referenced to VAG unless otherwise noted.

<sup>2</sup> Power Supply Rejection Ratio is for Longjing IC only. Total PSRR from battery to output is obtained by summing the PSRR from Neptune to the one from the Regulator in Seaweed. It is assumed that the regulators in Seaweed will have a minimum PSRR of 45 dB.

<sup>3</sup> For A/D differential input (ADC\_P - ADC\_M) 0dBm0 = 340mV<sub>rms</sub>.  
The codec output will not "foldback" or oscillate if overdriven, but clip.

<sup>4</sup> The digital word corresponding to +3dBm0 is '011111111111'b. Therefore if the audio level is set to +3dBm0, any variation in gain could cause large distortion if the digital number exceeds '011111111111'b. For this reason the maximum recommended signal for low distortion is +3dBm0 - (Absolute Gain Error) = +2dBm0.

<sup>5</sup> GSM Spec = -64 0dB.

<sup>6</sup> This value is a preliminary target. The final number will be specified after obtaining the production statistical data.

<sup>7</sup> Small frequency response deviation from straight line in the 60:200 Hz range is acceptable by spec requirements.

<sup>8</sup> Small frequency response deviation from straight line in the 3400:4000 Hz range is acceptable by spec requirements.

<sup>9</sup> Small frequency response deviation from straight line in the 3400:4000 Hz range is acceptable by spec requirements.

## Preliminary Electrical Characteristics

Figure 34 and Figure 35 show the filter frequency response for the audio signal for voice coding path. (All filter frequencies increase by 8.1/8.0 if VCLK is selected to generate  $f_{\text{SYNC}}=8.1\text{kHz}$ ).

<sup>1</sup> All analog signals are referenced to VAG unless otherwise noted. Output is 0dbm0 unless noted.

<sup>2</sup> For D/A differential output (CODEC\_DACP - CODEC\_DACN) 0dBm0 = 500 mV<sub>rms</sub>.

<sup>3</sup> GSM Spec = -64.

<sup>4</sup> Small frequency response deviation from straight line in the 60:200 Hz range is acceptable by spec requirements.

<sup>5</sup> Small frequency response deviation from straight line in the 3400:4000 Hz range is acceptable by spec requirements.

<sup>6</sup> Small frequency response deviation from straight line in the 3400:4000 Hz range is acceptable by spec requirements.

## Preliminary Electrical Characteristics

Figure 36 and Figure 37 show the filter frequency response for the audio signal for voice decoding. The requirements for the decoding path at 3.4 kHz are slightly different from the coding path. (All filter frequencies increase by 8.1/8.0 if VCLK is selected to generate  $f_{\text{SYNC}} = 8.1 \text{ kHz}$ ).
