

TPS6306x High Input Voltage, Buck-Boost Converter With 2-A Switch Current

1 Features

- Input voltage range: 2.5 V to 12 V
- Efficiency: Up to 93%
- Output current at 5 V ($V_{IN} < 10$ V): 2 A in buck mode
- Output current at 5 V ($V_{IN} > 4$ V): 1.3 A in boost mode
- Automatic transition between step down and boost mode
- Typical device quiescent current: $< 30 \mu\text{A}$
- Fixed and adjustable output voltage options from 2.5 V to 8 V
- Power save mode for improved efficiency at low output power
- Forced fixed-frequency operation at 2.4 MHz and synchronization possible
- Power good output
- Buck-Boost Overlap Control™
- Load disconnect during shutdown
- Overtemperature protection
- Overvoltage protection

2 Applications

- Dual Li-ion application
- Digital still cameras (DSC) and camcorders
- Notebook computer
- Industrial metering equipment
- Ultra mobile PCs and mobile internet devices
- Personal medical products
- High-power LEDs

Simplified Application

3 Description

The TPS6306x devices provide a power supply solution for products powered by either three-cell up to six-cell alkaline, NiCd or NiMH battery, or a one-cell or dual-cell Li-Ion or Li-polymer battery. Output currents can go as high as 2 A while using a dual-cell Li-Ion or Li-polymer battery, and discharge to 5 V or lower. The buck-boost converter is based on a fixed frequency, pulse width modulation (PWM) controller using synchronous rectification to obtain maximum efficiency. At low load currents, the converter enters power save mode to maintain high efficiency over a wide load current range. The power save mode can be disabled, forcing the converter to operate at a fixed switching frequency. The maximum average current in the switches is limited to a typical value of 2.25 A. The output voltage is programmable using an external resistor divider, or is fixed internally on the chip. The converter can be disabled to minimize battery drain. During shutdown, the load disconnects from the battery.

The devices are available in a 3 mm × 3 mm, 10-pin, WSON (DSC) package.

8 Detailed Description

8.1 Overview

The TPS6306x use 4 internal N-channel MOSFETs to maintain synchronous power conversion at all possible operating conditions. This enables the device to keep high efficiency over the complete input voltage and output power range. To regulate the output voltage at all possible input voltage conditions, the device automatically switches from buck operation to boost operation and back as required by the configuration. It always uses one active switch, one rectifying switch, one switch is held on, and one switch held off. Therefore, it operates as a buck converter when the input voltage is higher than the output voltage, and as a boost converter when the input voltage is lower than the output voltage. There is no mode of operation in which all 4 switches are switching at the same time. Keeping one switch on and one switch off eliminates their switching losses. The RMS current through the switches and the inductor is kept at a minimum, to minimize switching and conduction losses. Controlling the switches this way allows the converter to always keep higher efficiency.

The device provides a seamless transition from buck to boost or from boost to buck operation.

8.2 Functional Block Diagrams

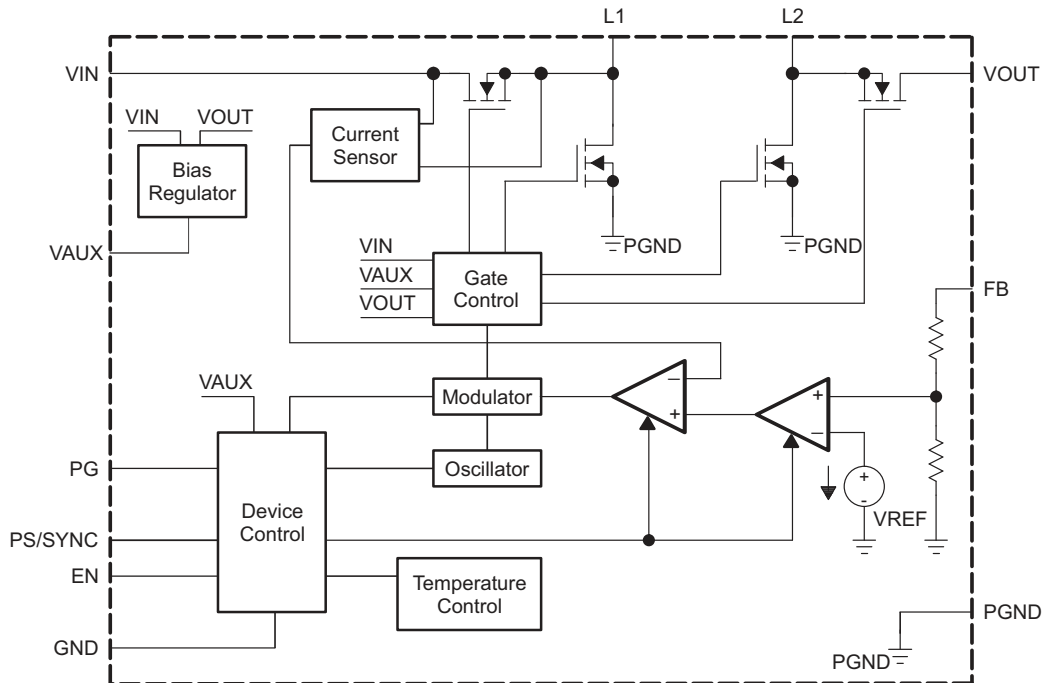

Figure 8-2. TPS63061 Fixed Output

8.3 Feature Description

8.3.1 Power Good

The device has a built in power good function to indicate whether the output voltage is regulated properly. As soon as the average inductor current gets limited to a value below the current the voltage regulator demands for maintaining the output voltage the power good output gets low impedance. The output is open drain, so its logic function can be adjusted to any voltage level the connected logic is using, by connecting a pull up resistor to the supply voltage of the logic. By monitoring the status of the current control loop, the power good output provides the earliest indication possible for an output voltage break down and leaves the connected application a maximum time to safely react.

8.3.2 Soft-Start Function

After being enabled, the device starts operating. The average current limit ramps up from an initial 400 mA following the output voltage increasing. At an output voltage of about 1.2 V, the current limit is at its nominal value. If the output voltage does not increase, the current limit does not increase. The device implements no timer. Thus, the output voltage overshoot at startup, as well as the inrush current, remains at a minimum. The device ramps up the output voltage in a controlled manner even if a large capacitor is connected at the output.

8.3.3 Short-Circuit Protection

When the output voltage does not increase above 1.2 V, the device assumes a short circuit at the output, and keeps the current limit low to protect itself and the application. During a short-circuit situation on the output, the device maintains the current limit below 2 A typically (minimum average inductance current).

8.3.4 Overvoltage Protection

If, for any reason, the output voltage is not fed back properly to the input of the voltage amplifier, control of the output voltage no longer works. Therefore, overvoltage protection is implemented to avoid the output voltage exceeding critical values for the device and possibly for the system it supplies. The implemented overvoltage protection circuit monitors the output voltage internally as well. If it reaches the overvoltage threshold, the voltage amplifier regulates the output voltage to this value.

8.3.5 Undervoltage Lockout

An undervoltage lockout function prevents device start-up if the supply voltage on VIN is lower than approximately its threshold (see the [Section 7.5](#) table). When in operation, the device automatically enters the shutdown mode if the voltage on VIN drops below the undervoltage lockout threshold. The device automatically restarts if the input voltage recovers to the minimum operating input voltage.

8.3.6 Overtemperature Protection

The device has a built-in temperature sensor which monitors the internal device temperature. If the temperature exceeds the programmed threshold (see the [Section 7.5](#) table) the device stops operating. As soon as the device temperature has decreased below the programmed threshold, it starts operating again. There is a built-in hysteresis to avoid unstable operation at device temperatures at the overtemperature threshold.

8.4 Device Functional Modes

8.4.1 Buck-Boost Operation

To regulate the output voltage at all possible input voltage conditions, the device automatically switches from buck operation to boost operation and back as required. It always uses one active switch, one rectifying switch, one switch permanently on, and one switch permanently off. Therefore, it operates as a step down converter (buck) when the input voltage is higher than the output voltage, and as a boost converter when the input voltage is lower than the output voltage. There is no mode of operation in which all 4 switches are permanently switching. Controlling the switches this way allows the converter to maintain high efficiency at the most important point of operation, when the input voltage is close to the output voltage. The RMS current through the switches and the inductor is kept at a minimum, to minimize switching and conduction losses.

8.4.2 Control Loop

The controller circuit of the device is based on an average current mode topology. The average inductor current is regulated by a fast current regulator loop which is controlled by a voltage control loop. [Figure 8-3](#) shows the control loop.

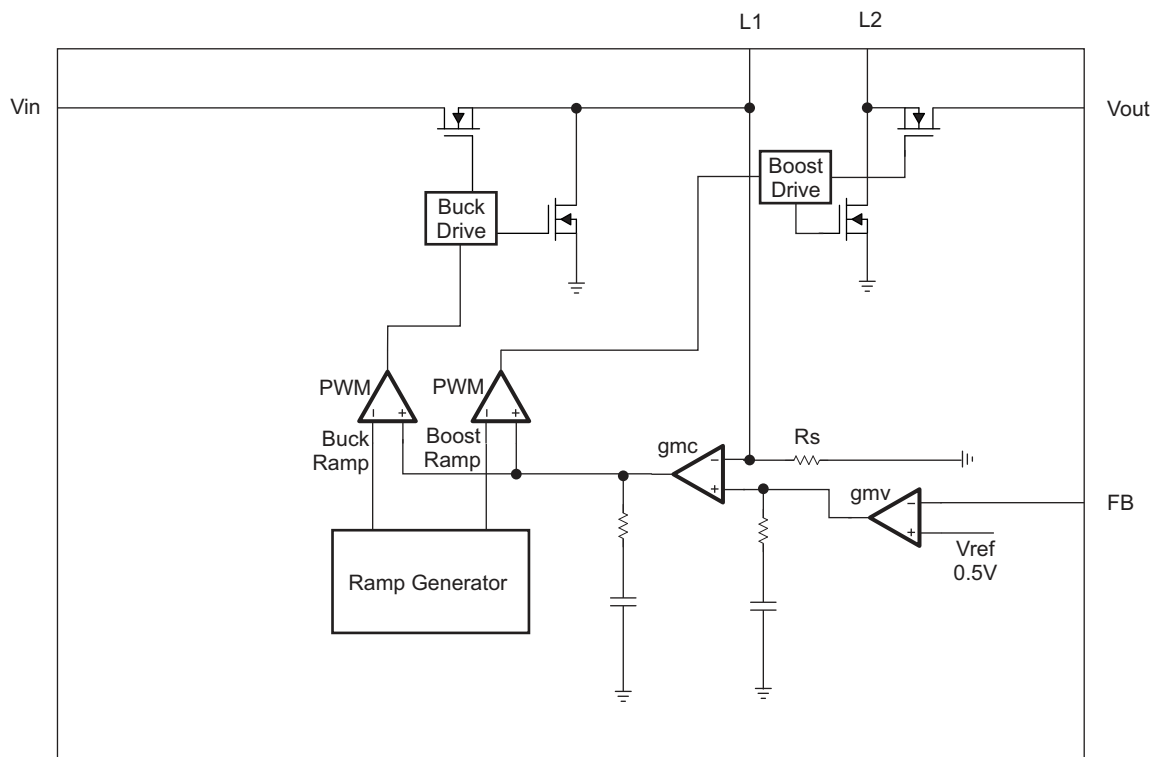

Figure 8-3. Average Current Mode Control

The non inverting input of the transconductance amplifier, g_{MV} , is assumed to be constant. The output of g_{MV} defines the average inductor current. The inductor current is reconstructed by measuring the current through the high side buck MOSFET. This current corresponds exactly to the inductor current in boost mode. In buck mode the current is measured during the on time of the same MOSFET. During the off time, the current is reconstructed internally starting from the peak value at the end of the on-time cycle. The average current is compared to the desired value and the difference, or current error, is amplified and compared to the buck or the boost sawtooth ramp. Depending on which of the two ramps the g_{MC} amplified output crosses, the device activates either the buck MOSFETs or the boost MOSFETs. When the input voltage is close to the output voltage, one boost cycle always follows a buck cycle. In this condition, no more than three cycles in a row of the same mode are allowed. This control method in the buck-boost region ensures a robust control and the highest efficiency.

8.4.3 Power-Save Mode

The PS/SYNC pin can be used to select different operation modes. Power save mode improves efficiency at light load. To enable power save mode, PS/SYNC must be set low. The device enters power save mode when the average inductor current falls to a level lower than approximately 100 mA. In that situation, the converter operates with reduced switching frequency and with a minimum quiescent current to maintain high efficiency.

During the power save mode operation, the output voltage is monitored with a comparator by the threshold comparator low and comparator high. When the device enters power save mode, the converter stops operating and the output voltage drops. The slope of the output voltage depends on the load and the value of output capacitance. As the output voltage falls below the comparator low threshold set to 2.5% typical above the output voltage, the device ramps up the output voltage again, by starting operation using a programmed average inductor current higher than required by the current load condition. Operation can last for one or several pulses. The converter continues these pulses until the comparator high threshold, set to typically 3.5% above the nominal output voltage, is reached and the average inductor current gets lower than about 100 mA. When the load increases above the minimum forced inductor current of about 100 mA, the device automatically switches to PWM mode.

The power save mode can be disabled by programming the PS/SYNC high.

Figure 8-4. Power-Save Mode Thresholds and Dynamic Voltage Positioning

8.4.4 Synchronization

Connecting a clock signal at PS/SYNC forces the device to synchronize to the connected clock frequency.

Synchronization is done by a PLL to lower and higher frequencies compared to the internal clock. The PLL can also tolerate missing clock pulses without the converter malfunctioning. The PS/SYNC input supports standard logic thresholds.

8.4.5 Dynamic Voltage Positioning

The output voltage is typically 3% above the nominal output voltage at light-load currents, as the device is operating in power save mode. This operation mode allows additional headroom for the voltage drop during a load transient from light load to full load. This additional headroom allows the converter to operate with a small

output capacitor and maintain a low absolute voltage drop during heavy load transient changes. See [Figure 8-4](#) for detailed operation of the power save mode operation.

8.4.6 Dynamic Current Limit

The dynamic current limit function maintains the output voltage regulation when the power source becomes weaker. The maximum current allowed through the switch depends on the voltage applied at the input terminal of the TPS6306x devices. [Figure 8-5](#) shows this dependency, and the I_{SW} vs V_{IN} . The dynamic current limit has its lowest value when reaching the minimum recommended supply voltage at V_{IN} .

Given the I_{SW} value from [Figure 8-5](#), is then possible to calculate the output current reached in boost mode using [Equation 1](#) and [Equation 2](#) and in buck mode using [Equation 3](#) and [Equation 4](#).

$$\text{Duty Cycle Boost} \quad D = \frac{V_{OUT} - V_{IN}}{V_{OUT}} \quad (1)$$

$$\text{Maximum Output Current Boost} \quad I_{OUT} = \eta \times I_{SW} \times (1 - D) \quad (2)$$

$$\text{Duty Cycle Buck} \quad D = \frac{V_{OUT}}{V_{IN}} \quad (3)$$

$$\text{Maximum Output Current Buck} \quad I_{OUT} = I_{SW} \quad (4)$$

where

- η is the estimated converter efficiency (use the number from the efficiency curves or 0.80 as an assumption)
- f is the converter switching frequency (typical 2.4 MHz)
- L is the selected inductor value

If the die temperature increases above the recommended maximum temperature, the dynamic current limit becomes active. The current limit is reduced with temperature increasing.

Figure 8-5. Average Inductance Current vs Input Voltage

8.4.7 Device Enable

The device operates when EN is set high. The device enters a shutdown sequence when EN is set to GND. During the shutdown sequence, the regulator stops switching, all internal control circuitry is switched off, and the load is disconnected from the input. It is possible for the output voltage to drop below the input voltage during shutdown. During the start-up sequence, the device limits the duty cycle and the peak current in order to avoid high peak currents flowing from the input.

9 Application and Implementation

Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The TPS6306x devices provide a power supply solution for products powered by either three-cell up to six-cell alkaline, NiCd or NiMH battery, or a one-cell or dual-cell Li-Ion or Li-polymer battery. Output currents can go as high as 2-A while using a dual-cell Li-Ion or Li-polymer battery, and discharge it down to 5 V or lower.

9.2 Typical Application

9.2.2 Detailed Design Procedure

The first step is the selection of the output filter components. To simplify this process, use [Table 9-2](#) to compare inductor and capacitor value combinations.

9.2.2.1 Step One: Output Filter Design

Table 9-2. Output Capacitor and Inductor Combinations

Inductor Value [μH] ⁽¹⁾	Output Capacitor Value [μF] ⁽²⁾		
	44	66	100
1.0	√	√ ⁽³⁾	√
1.5	√	√	√

- (1) Inductor tolerance and current de-rating is anticipated. The effective inductance can vary by 20% and –30%.
- (2) Capacitance tolerance and bias voltage de-rating is anticipated. The effective capacitance can vary by 20% and –50%.
- (3) Typical application. Other check mark indicates recommended filter combinations

9.2.2.2 Step Two: Inductor Selection

The inductor selection is affected by several parameters including inductor ripple current, output voltage ripple, transition point into power-save mode, and efficiency. See [Table 9-3](#) for typical inductors.

Table 9-3. List of Recommended Inductors

Inductor Value (μH)	Component Supplier ⁽¹⁾	Size (L×W×H) (mm)	Current Saturation (I_{SAT}) (A)	DCR (m Ω)
1	Coilcraft XFL4020-102	4 × 4 × 2.1	5.1	10.8
1	TOKO DEM2815 1226AS-H-1R0N	3 × 3.2 × 1.5	2.7	27
1.5	Coilcraft XFL4020-152	4 × 4 × 2.1	4.4	14.4

- (1) See [Section 12.1](#)

For high efficiencies, the inductor should have a low dc resistance to minimize conduction losses. Especially at high-switching frequencies the core material has a higher impact on efficiency. When using small chip inductors, the efficiency is reduced mainly due to higher inductor core losses. This needs to be considered when selecting the appropriate inductor. The inductor value determines the inductor ripple current. The larger the inductor value, the smaller the inductor ripple current and the lower the conduction losses of the converter. Conversely, larger inductor values cause a slower load transient response. To avoid saturation of the inductor, with the chosen inductance value, the peak current for the inductor in steady state operation can be calculated. [Equation 1](#) and [Equation 5](#) show how to calculate the peak current I_{PEAK} . Only the equation which defines the switch current in boost mode is reported because this is providing the highest value of current and represents the critical current value for selecting the right inductor.

$$I_{\text{PEAK}} = \frac{I_{\text{OUT}}}{\eta \times (1-D)} + \frac{V_{\text{IN}} \times D}{2 \times f_{\text{SW}} \times L} \quad (5)$$

where

- D is the duty cycle during boost mode operation
- f_{SW} is the converter switching frequency (typical 2.4 MHz)
- L is the selected inductor value
- η is the estimated converter efficiency (use the number from the efficiency curves or 0.80 as an assumption)
- The calculation must be done for the minimum input voltage which is possible to have in boost mode

Calculating the maximum inductor current using the actual operating conditions gives the minimum saturation current of the inductor needed. It's recommended to choose an inductor with a saturation current 20% higher than the value calculated using [Equation 5](#). Possible inductors are listed in [Table 9-3](#).

9.2.2.3 Step Three: Capacitor Selection

9.2.2.3.1 Input Capacitors

To improve transient behavior of the regulator and EMI behavior of the total power supply circuit, this design suggests a minimum input capacitance of 20 μF . Place a ceramic capacitor placed as close as possible to the VIN and PGND pins of the device.

9.2.2.3.2 Output Capacitor

For the output capacitor, use of a small ceramic capacitor placed as close as possible to the VOUT and PGND pins of the device is recommended. If, for any reason, the application requires the use of large capacitors which can not be placed close to the device, use a smaller ceramic capacitor in parallel to the large capacitor. The small capacitor should be placed as close as possible to the VOUT and PGND pins of the device. The recommended typical output capacitor value is 66 μF with a variance as outlined in [Table 9-1](#).

There is also no upper limit for the output capacitance value. Larger capacitors cause lower output voltage ripple as well as lower output voltage drop during load transients.

When choosing input and output capacitors, it needs to be kept in mind, that the value of capacitance experiences significant losses from their rated value depending on the operating temperature and the operating DC voltage. It is not uncommon for a small surface mount ceramic capacitor to lose 50% and more of its rated capacitance. For this reason, it is important to use a larger value of capacitance or a capacitor with higher voltage rating in order to ensure the required capacitance at the full operating voltage.

9.2.2.3.3 Bypass Capacitor

To make sure that the internal control circuits are supplied with a stable low noise supply voltage, a capacitor is connected between VAUX and GND. Using a ceramic capacitor with a value of 0.1 μF is recommended. The capacitor needs to be placed close to the VAUX pin. The value of this capacitor should not be higher than 0.22 μF .

9.2.2.4 Step Four: Setting the Output Voltage

When the adjustable output voltage version TPS63060 is used, the output voltage is set by the external resistor divider. The resistor divider must be connected between VOUT, FB and GND. When the output voltage is regulated properly, the typical value of the voltage at the FB pin is 500mV. The maximum recommended value for the output voltage is 8V. The current through the resistive divider should be about 100 times greater than the current into the FB pin. The typical current into the FB pin is 0.01 μA , and the voltage across the resistor between FB and GND, R_2 , is typically 500 mV. Based on these two values, the recommended value for R_2 should be lower than 500 $\text{k}\Omega$, in order to set the divider current at 3 μA or higher. It is recommended to keep the value for this resistor in the range of 200 $\text{k}\Omega$. From that, the value of the resistor connected between the VOUT pin and the FB pin, (R_1) depending on the needed output voltage can be calculated using [Equation 6](#).

$$R_1 = R_2 \times \left(\frac{V_{\text{OUT}}}{V_{\text{FB}}} - 1 \right) \quad (6)$$

Place a small capacitor (C_4 , 10 pF) in parallel with R_2 when using the power save mode and the adjustable version, to provide filtering and improve the efficiency at light load.

10 Power Supply Recommendations

The TPS6306x device family has no special requirements for its input power supply. The input supply output current must be rated according to the supply voltage, output voltage and output current of the TPS6306x.

11 Layout

11.1 Layout Guidelines

For all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground tracks. The input capacitor, output capacitor, and the inductor should be placed as close as possible to the device. Use a common ground node for power ground and a different one for control ground to minimize the effects of ground noise. Connect these ground nodes at any place close to one of the ground pins of the device.

The feedback divider should be placed as close as possible to the control ground pin of the device. To lay out the control ground, short traces are recommended as well, separation from the power ground traces. This avoids ground shift problems, which can occur due to superimposition of power ground current and control ground current.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.
