

# Intel® Enpirion® Power Solutions EM2280P01QI 80A PowerSoC

## Step-Down DC-DC Switching Converter with Integrated Inductor, Featuring Digital Control with PMBus™ v1.2 Compliant Interface

## **Description**

The EM2280 is a fully integrated 80A PowerSoC synchronous dual-phase buck converter. It features an advanced digital controller, gate drivers, synchronous MOSFETs, and high-performance inductors. Only input and output filter capacitors and a few small signal components are required for a complete solution. A PMBus version 1.2 compliant interface provides setup, control, and telemetry.

Differential remote sensing and ±0.5% set-point accuracy provides precise regulation over line, load and temperature variation. Very low ripple further reduces accuracy uncertainty to provide best in class static regulation for today's FPGAs, ASICs, processors, and DDR memory devices.

The EM2280 can be configured and controlled in any application by two methods, either in pin-strap mode using onboard resistors, or using the PMBUS interface. The customer can also configure the device during engineering evaluation using the PMBUS interface, which offers a high degree of flexibility and programmability, and then use the pin strap mode when devices are deployed in production. Advanced digital control techniques stability and excellent ensure performance, and eliminate the need for external compensation components. The Intel Enpirion Digital Power Configurator provides a user-friendly and easy-to-use interface for communicating with and configuring the device.

The EM2280 features high conversion efficiency and superior thermal performance to minimize thermal de-rating limitations, which is key to product reliability and longevity.

#### **Features**

- Integrated digital controller, inductors and FETs
- Wide 4.5V to 16V V<sub>IN</sub> range
- 0.5V to 1.3V V<sub>OUT</sub> range
- 80A continuous current with no thermal derating upto 80°C (12Vin, 0.9Vout)
- 23mm x 18mm x 6.8mmmm QFN package
- Peak efficiency of 92% at  $V_{IN} = 12V_{,}V_{OUT} = 1.3V_{,}$
- Meets all high-performance FPGA requirements o Digital loop for best in class transient response 0.5% set-point over line, load, temperature

  - Output ripple as low as 10 mV peak-peak
  - o Differential remote sensing
  - Monotonic startup into pre-bias output
  - Optimized FPGA configs stored in NVM
- Programmable through PMBus ○Vout margining, startup and shutdown delays

o Programmable warnings, faults and response

- Operational without PMBus
  - RVSET resistor for setting V<sub>OUT</sub>
  - RTUNE resistor for single resistor based compensation
- Programmable Overcurrent Response oLatch Off (default) OHiccup
- Tracking pin for complex sequencing
- RoHS compliant, MSL level 3, 260°C reflow

#### **Applications**

- High performance FPGA Core Supply
- ASIC and processor supply rails

## **Ordering Information**

Table 1

| Part Number       | Supported V <sub>OUT</sub><br>Range | Package<br>Markings | Package Description  |  |
|-------------------|-------------------------------------|---------------------|--|--|
| EM2280P01QI       | 0.5V to 1.3V                        | M2280P              | 18 mm x 23 mm x 6.8mm QFN152 provided in 48 units per tray |  |

# **Pin Description**

Table 2

| PIN   | NAME   | I/O                 | FUNCTION   |
|---|--------|---------------------|--|
| 1-5, 105-<br>153  | VOUT   | Regulated<br>Output | Regulated output voltage. Decouple to PGND with appropriate filter capacitors  |
| 6   | POK    | Digital I/O         | Power OK is an open drain transistor for power system state indication. See the Power OK description for details.  |
| 7   | CTRL   | Digital<br>Input    | PMBus-compatible control pin with programmable functionality. CTRL should never be left floating if enabled in Configuration. The default configuration is for $V_{\text{OUT}}$ to be on with CTRL high (positive edge)  |
| 8   | SALRT  | Digital<br>Output   | PMBus™ alert line.   |
| 9   | VDD33  | Output              | 3.3V output of the internal LDO. May be used as pull-up supply for PMBus™ pins and CTRL pin.   |
| 10  | VCC    | Input<br>Supply     | 5.0V supply voltage for analog circuitry.  |
| 11  | SDA    | Digital I/O         | PMBus™ serial data I/O.  |
| 12  | SCL    | Digital I/O         | PMBus™ serial clock input.   |
| 15  | PWM0   | PWM                 | Phase 0 PWM signal test pin.   |
| 13-14,<br>16-18,<br>25, 55,<br>85, 92,<br>93, 95,<br>96 | NC     | NC                  | No connect. Do not connect to any signal, supply, or ground.   |
| 19-24,<br>86-91,<br>155                                 | PVIN   | Input<br>Supply     | Input supply for MOSFET switches. Decouple to PGND with appropriate filter capacitors. Refer to Recommended Application Circuit section for more details.  |
| 26-53,<br>57-84,<br>154,156                             | PGND   | Ground              | Power ground. Ground for MOSFET switches.  |
| 54  | PH0    | PHASE               | PHASE 0 signal test pin.   |
| 56  | PH1    | PHASE               | PHASE 1 signal test pin.   |
| 94  | PWM1   | PWM                 | Phase 1 PWM signal test pin.   |
| 97  | VSENP  | Analog<br>Input     | Differential output voltage sense input (positive).  |
| 98  | VSENN  | Analog<br>Input     | Differential output voltage sense input (negative).  |
| 99  | VTRACK | Analog<br>Input     | Voltage tracking reference input if EM2280 is configured for voltage tracking mode. Voltage tracking mode is not enabled in the default configuration. May remain floating, if not used (Default configuration). If voltage tracking mode is used (Or enabled), refer to Functional Description section. |
| 100   | ADDRO  | Analog<br>I/O       | A resistor from ADDR0 to PGND can be used to set the PMBus™ address. Use a 1% tolerance or better resistor.  |
| 101   | ADDR1  | Analog<br>I/O       | A resistor from ADDR1 to PGND can be used to set the PMBus™ address. Use a 1% tolerance or better resistor.  |

| PIN | NAME  | I/O           | FUNCTION   |
|-----|-------|---------------|--|
| 102 | RVSET | Analog<br>I/O | A resistor from RVSET to PGND can be used to program the $V_{\text{OUT}}$ set-point. Using 1% tolerance or better resistor.  |
| 103 | RTUNE | Analog<br>I/O | A resistor from RTUNE to PGND can be used to tune the transient compensator for output capacitance. Using 1% tolerance or better resistor.   |
| 104 | SYNC  | Digital I/O   | SYNC is not enabled in the default configuration. May remain floating, if not used (default configuration). If SYNC is used (Or enabled), refer to Functional Description Section. |

## **Absolute Maximum Ratings**

**CAUTION**: Absolute Maximum ratings are stress ratings only. Functional operation beyond the recommended operating conditions is not implied. Stress beyond the absolute maximum ratings may impair device life. Exposure to absolute maximum rated conditions for extended periods may affect device reliability. Voltage measurements are referenced to PGND.

## **Absolute Maximum Pin Ratings**

Table 3

| PARAMETER                  | SYMBOL                                | MIN  | MAX         | UNITS |

## **Recommended Operating Conditions**

#### Table 6

| PARAMETER                      | PINS             | MIN  | MAX  | UNITS |
|--------------------------------|------------------|------|------|-------|
| PVIN supply voltage range      | PVIN             | 4.5  | 16   | V     |
| Supply voltage V <sub>CC</sub> | VCC              | 4.75 | 5.25 | V     |
| Continuous load current        | V <sub>OUT</sub> |      | 80   | Α     |
| Junction Temperature (Note 1)  |                  | -40  | 125  | °C    |

(Note 1): OTP default is set to 120°C for safety margin

## **Thermal Characteristics**

#### Table 7

| PARAMETER  | PINS              | TYPICAL | UNITS |
|--|-------------------|---------|-------|
| Thermal shutdown [programmable]                          | $T_{SD}$          | 120     | °C    |
| Thermal shutdown Hysteresis                              | T <sub>SDH</sub>  | 18      | °C    |
| Thermal resistance: junction to ambient (0 LFM) (Note 1) | $\theta_{\sf JA}$ | 7.25    | °C/W  |
| Thermal resistance: junction to case bottom (0 LFM)      | θις               | 1.35    | °C/W  |

**Note 1:** Based on 2 oz. external copper layers and proper thermal design in line with EIJ/JEDEC JESD51 standards for high thermal conductivity boards. No top side cooling required.

## **Electrical Characteristics**

 $PV_{IN}$  = 12V and  $V_{CC}$  = 5.0V. The minimum and maximum values are over the operating ambient temperature range (-40°C to 85°C) unless otherwise noted. Typical values are at  $T_A$  = 25°C.

## **Functional Block Diagram**

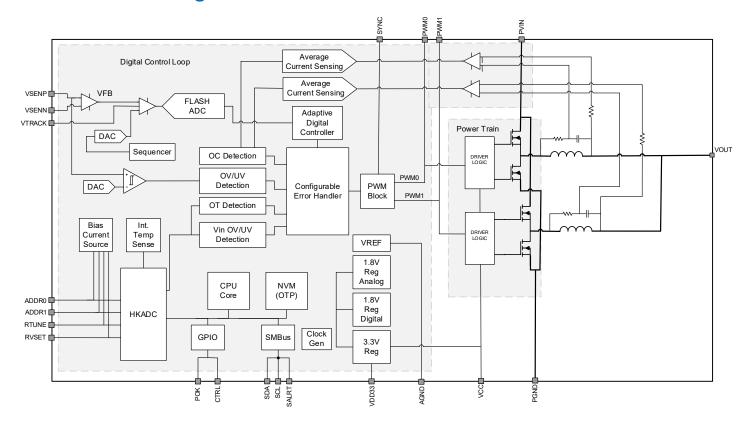

Figure 3: Functional Block Diagram

## **Functional Description**

#### **FUNCTIONAL DESCRIPTION: DEFAULT CONFIGURATION**

The EM2280 is a two-phase, single output digital PowerSoC synchronous step-down converter with advanced digital control techniques, capable of supplying up to 80A of continuous output current. The PowerSoC includes integrated power MOSFETs, high-performance inductors and a digital controller which offers a PMBus version 1.2 compliant interface to support an extensive suite of telemetry, configuration and control commands.

In the default configuration, the EM2280 requires only two resistors total to set the output voltage and set the digital compensator for the most optimized performance. This easy-to-use default configuration allows the user to tune the EM2280 to meet the most demanding accuracy and load transient requirements without requiring any programming or digital interface. The following sections describe the default configuration. Refer to the Advanced Configuration section for details on the many ways the EM2280 may be customized and configured through the PMBus interface.

The advanced digital control loop works as a voltage-mode controller using a PID-type compensation. The basic structure of the controller is shown in **Figure 4**. The EM2280 controller features two PID compensators for steady-state operation and fast transient operation. Fast, reliable switching between the different compensation modes ensures good transient performance and quiet steady state performance. The EM2280

has been pre-programmed with a range of default compensation coefficients which lets the user select the best compensation for the best transient response and stability for the output capacitance of the system.

The EM2280 uses two additional technologies to improve transient performance. First, the EM2280 uses over-sampling techniques to acquire fast, accurate, and continuous information about the output voltage so that the device can react quickly to any changes in output voltage. Second, a non-linear gain adjustment is applied during large load transients to boost the loop gain and reduce the settling time.

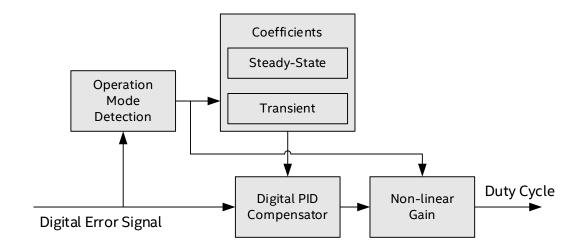

Figure 4: Simplified Block Diagram Of The Digital Compensation

In the default configuration, the EM2280 offers a complete suite of fault warnings and protections. Input and output Under Voltage Lock-Out (UVLO) and Over Voltage Lock-Out (OVLO) conditions are continuously monitored. A dedicated ADC is used to provide fast and accurate current information over the switching period allowing for fast Over-Current Protection (OCP) response. Over Temperature Protection (OTP) is accomplished by direct monitoring of the internal controller's temperature and also the temperature of both Power Trains.

#### **POWER ON RESET**

The EM2280 employs an internal power-on-reset (POR) circuit to ensure proper start-up and shut down with a changing supply voltage. Once the VCC supply voltage increases above the POR threshold voltage, the EM2280 begins the internal start-up process. Upon its completion, the device is ready for operation.

Two separate input voltage supplies are necessary to operate, PVIN (4.5V to 16V) and  $V_{CC}$  (4.75V to 5.25V). Both of these voltage rails are internally monitored for proper power-up and to protect the power MOSFETs under various input power fault conditions.

The EM2280 also uses the PVIN monitor for input voltage feed-forward, which eliminates variations in the output voltage due to sudden changes in the input voltage supply. It does this by immediately changing the duty cycle to compensate for the input supply variation by normalizing the DC gain of the loop.

#### SETTING THE OUTPUT VOLTAGE

Differential remote sensing provides for precise regulation at the point of load. One of thirty output voltages may be selected in the default configuration, based on a resistor connected to the RVSET pin. At power-up, an internal current source biases the resistor and the voltage is measured by an ADC to decode the Vout selection. Use **Table 9** for the details of V<sub>OUT</sub> selection and RVSET values.

The digital control loop ADC of the EM2280 supports direct output voltage feedback connection over the entire  $V_{\text{OUT}}$  range.

**Note**: at output voltage <0.7V, high PVin values >10V and very light loads, pulse skipping may occur on the PWM which may result in a slight increase in output ripple. This is the due to the very narrow PWM outputs resulting from these conditions and the minimum pulse width accepted by the Power Trian to ensure no cross conduction between the Top and Bottom MOSFET's.

Table 9: Supported Configuration Voltage Values for EM2280P01 Output Voltage

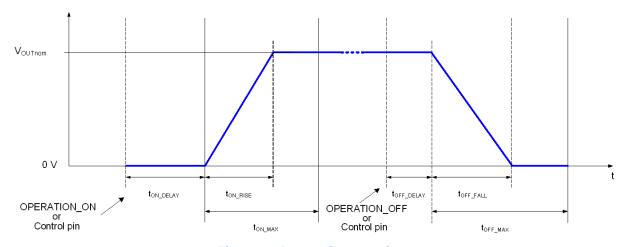

| RVSET Resistor<br>(1% tolerance or better<br>resistor) | V <sub>оит</sub> |
|--|------------------|
| 0kΩ  | Reserved         |
| 0.392kΩ  | Reserved         |
| 0.576kΩ  | 1.3V             |
| 0.787kΩ  | 1.25V            |
| 1.000kΩ  | 1.2V             |
| 1.240kΩ  | 1.175V           |
| 1.500kΩ  | 1.15V            |
| 1.780kΩ  | 1.12V            |

| 6.040kΩ  | 0.89             |
| 6.810kΩ  | 0.875V           |
| 7.680kΩ  | 0.85V            |
| 8.660kΩ  | 0.825V           |
| 9.530kΩ  | 0.8V             |

| RVSET Resistor<br>(1% tolerance or better<br>resistor) | V <sub>OUT</sub> |
|--|------------------|
| 10.500kΩ   | 0.775V           |
| 11.800kΩ   | 0.75V            |
| 13.000kΩ   | 0.72V            |
| 14.300kΩ   | 0.7V             |
| 15.800kΩ   | 0.65V            |
| 17.400kΩ   | 0.6V             |
| 19.100kΩ   | 0.55V            |
| 21.000kΩ   | 0.52V            |
| 23.200kΩ   | 0.5V             |

#### **ENABLE AND OUTPUT START-UP BEHAVIOR**

The control pin (CTRL) provides a means to enable normal operation or to shut down the device. When the CTRL pin is asserted (high) the device will undergo a normal soft-start. A logic low on this pin will power the device down in a controlled manner. Dedicated pre-biased start-up logic ensures proper start-up of the power converter when the output capacitors are pre-charged to a non-zero output voltage. Closed-loop stability is ensured during this period.

The typical power sequencing, including ramp up/down and delays is shown in Figure 5.

**Figure 5: Power Sequencing** 

#### **POWER OK**

The EM2280 has a Power OK indicator at its output pin POK, which is Open Drain and therefore requires a pull-up resistor. The Pull-Up resistor may be connected to the VDD33 pin but it is not recommended to use the 5VCC supply. When de-asserted, POK indicates that the output voltage is below the threshold value, 90% of the programmed output voltage in the default configuration. When asserted, POK indicates that the output is in regulation, and no major faults are present. As a result, POK de-asserts during any serious fault condition where power conversion stops and re-asserts when the output voltage recovers.

In a noisy application, it is strongly recommended that a 100nF decoupling capacitor be placed between the POK pin and GND to act as a filter to unwanted external noise.

#### **SMBALERT**

The SMBAlert pin is intended to operate using an external pull-up voltage of 3.3V and contains a weak internal pull-up.

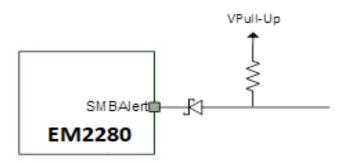

Figure 6. Power Sequencing

If operating in applications with a lower pull-up voltage, it is recommended that an external low Vf Schottky diode be placed at the input to localise this voltage.

**Table 10. Schottky Diode Part Numbers** 

| Description                  | Manufacturer | P/N        |
|------------------------------|--------------|------------|
| 40V, 300mA, Schottky, SOD523 | ST           | BAT54KFILM |
| 40V, 250mA, Schottky, SOD523 | Diode Inc    | BAT64T5Q   |

#### COMPENSATING THE DIGITAL CONTROL LOOP

To improve the transient performance for a typical point-of-load design, it is common to add output capacitance to the converter. This moves the output LC resonant frequency lower as capacitance increases which results in lower bandwidth, lower phase margin, and longer settling times unless the control loop is compensated for added capacitance.

However, with EM2280 the user does not need to be concerned with, or even understand, the details of control loop compensation techniques. The default configuration allows users to select from preconfigured PID control loop settings (known as compensators) through the use of pin-strapping. A single resistor from the RTUNE pin to GND informs the EM2280 of the compensator selection.

The selection of the compensator is driven first by the type of output capacitors used, as the ESL and ESR of different capacitor types demands different PID coefficients to optimize transient deviation and recovery

characteristics. The default compensator is a design with a combination of ceramic and polymer capacitors, i.e. POSCAP.

Table 1 shows typical output capacitor part number recommendations.

The five different compensators can then be subdivided into groups of six each whereby the initial capacitance value in the appropriate compensator can be scaled upwards by multiplication factor M to match the additional capacitance.

Table 11: RTUNE configuration table for EM2280P01

| Compensator Description  | Соит       | RTUNE Resistor<br>(1% tolerance or better<br>resistor) | Multiplication<br>factor (M) | Typical Deviation with 50% Load Step |
|--|------------|--|------------------------------|--------------------------------------|

#### OUTPUT CAPACITOR RECOMMENDATION

EM2280 is designed for fast transient response and low output ripple noise. The output capacitors should be a mix of low ESR polymer and ceramic capacitors. **Table 11** shows different output capacitor combinations to optimize the load transient deviation performance. With the RTUNE feature, the user can simply scale up the total output capacitance to meet further stringent transient requirement.

Please consult the documentation for your particular FPGA, ASIC, processor, or memory block for the transient and the bulk decoupling capacitor requirements.

#### INPUT CAPACITOR RECOMMENDATION

The EM2280 PVIN input should be decoupled with at least four  $22\mu F$  1206 case size ceramic capacitors. More bulk capacitor may be needed if there are long inductive traces at the input source, there is not enough source capacitance or at low PVIN values.

These input decoupling ceramic capacitors may be mounted on the PCB back-side to reduce the solution size. These input filter capacitors should have the appropriate voltage rating for the input voltage on PVIN, and use a X5R, X7R, or equivalent dielectric rating. Y5V or equivalent dielectric formulations must not be used as these lose too much capacitance with frequency, temperature and bias voltage.

**Table 12: Recommended Output Capacitors** 

| Description                    | Manufacturer | P/N              |
|--------------------------------|--------------|------------------|
| 470μF, 2.5V, ESR 3mΩ SP-CAP    | Panasonic    | EEFGX0E471R      |
| 100μF, 6.3V, X5R, 1206 Ceramic | Kemet        | C1206C107M9PACTU |

#### **PROTECTION FEATURES**

The EM2280 offers a complete suite of programmable fault warnings and protections. Input and output Under Voltage Lock-Out (UVLO) and Over Voltage Lock-Out (OVLO) conditions are continuously monitored. A dedicated ADC is used to provide fast and accurate current information during the entire switching period to provide fast Over-Current Protection (OCP) response.

To prevent damage to the load, the EM2280 utilizes an output over-voltage protection circuit. The voltage at VSENP is continuously compared with a configurable threshold using a high-speed analog comparator. If the voltage exceeds the configured threshold, a fault response is generated and the PWM output is turned off.

The output voltage is also sampled, filtered, and compared with an output over-voltage warning threshold. If the output voltage exceeds this threshold, a warning is generated and the preconfigured actions are triggered. The EM2280 also monitors the output voltage with two lower thresholds. If the output voltage is below the under-voltage warning level and above the under-voltage fault level, an output voltage under-voltage warning is triggered. If the output voltage falls below the fault level, a fault event is generated.

Similar to output over and under voltage protection, the EM2280 monitors the input voltage at VINSEN continuously with a configurable threshold. If the input voltage exceeds the over voltage threshold or is below the under voltage threshold, the default response is generated.

Over Temperature Protection (OTP) is based on direct monitoring of the device's internal controller temperature and the internal Power Train temperature. If the temperature exceeds either OTP thresholds, the device will enter a soft-stop mode slowly ramping the output voltage down until the temperature falls below the default recovery temperature.

The default fault response is zero delay and latch off for most fault conditions. The CTRL pin may be cycled to clear the latch. **Table 13** summarizes the default configurations that have been pre-programmed to the device.

Fault Level Delay (ms) Signal Default Response Type Retries Warning Output Over-Voltage 0 None High-impedance Fault Warning 0 Output Under-Voltage None Fault High-impedance Warning 0 Input Over-Voltage None Fault High-impedance Warning 0 Input Under-Voltage Infinity Fault High-impedance Warning Over-Current 0 None Fault High-impedance Warning Controller Over-0 Temperature Fault Soft Off Infinity Warning Power Train Over-0 Infinity Temperature Fault Soft Off

**Table 13: Fault Configuration Overview** 

#### FUNCTIONAL DESCRIPTION: ADVANCED CONFIGURATION

All EM2280 modules are delivered with a pre-programmed default configuration, allowing the module to be powered up without a need to configure the device or even the need for the GUI to be connected. However, a PMBus version 1.2 compliant interface allows access to an extensive suite of digital communication and control commands. This includes configuring the EM2280 for optimum performance, setting various parameters such as output voltage, and monitoring and reporting device behavior including output voltage, output current, and fault responses.

The device may be reconfigured multiple times without storing the configuration into the non-volatile memory (NVM). Any configuration changes will be lost upon power-on reset unless specifically stored into NVM using either STORE\_DEFAULT\_ALL or STORE\_DEFAULT\_CODE PMBus commands. Please see **Table 16** for more details.

For RVSET and RTUNE configurations, there is no reprogramming permitted.

After writing a new configuration to NVM, the user may still make changes to the device configuration through the PMBus interface; however, now upon power cycling the device, the stored NVM configuration will be recalled upon power-up rather than the factory default configuration of the EM2280.

The NVM configuration can be stored three times in its entirety. However, the consumption of the available NVM is dynamic, based on the configuration parameters that have actually changed. The unused NVM information is given in the GUI or through the manufacture specific command MFR\_STORE\_PARAMS\_REMAINING.

#### INTEL DIGITAL POWER CONFIGURATOR

The Intel Enpirion Digital Power Configurator is a Graphical User Interface (GUI) software which allows the EM2280 to be controlled via a USB interface to a host computer.

The user can view the power supply's status, I/O voltages, output current and fault conditions detected by the device, program settings to the converter, and issue PMBus commands using the GUI. Most of the parameters (for example, VOUT turn on/off time, protection and fault limits) can be configured and adjusted within the GUI environment. These parameters can also be configured outside of the GUI environment using the relevant PMBus™ commands.

The GUI also allows the user to easily create, modify, test and save a configuration file which may then be used to permanently burn the configuration into NVM within a production test environment.

#### ALTERNATIVE OUTPUT VOLTAGE CONTROL METHODS

In the default configuration, output voltage selection is determined at power-up by the pin-strapped resistor RVSET. This functionality can be disabled using the PMBus command MFR\_PIN\_CONFIG. When RVSET is disabled, the output voltage will be determined by the nominal output voltage setting in the user configuration. The EM2280 supports a subset of the output voltage commands outlined in the PMBus specification. For example, the output voltage can be dynamically changed using the PMBus command VOUT\_COMMAND. When the output is being changed by the PMBus command, POK remains at a logic high.

#### POWER SEQUENCING AND THE CONTROL (CTRL) PIN

Three different configuration options are supported to enable the output voltage. The device can be configured to turn on after an OPERATION\_ON command, via the assertion of the CTRL pin or a combination of both per the PMBus convention. The EM2280 supports power sequencing features including programmable ramp up/down and delays. The typical sequence of events is shown in **Figure 5** and follows the PMBus standard. The individual timing values shown in **Figure 5** and **Figure 7** can be configured using the appropriate configuration setting in Intel Digital Power Configurator GUI.

#### PRE-BIASED START-UP AND SOFT-STOP

In systems with complex power architectures, there may be leakage paths from one supply domain which may charge capacitors in another supply domain, leading to a pre-biased condition on one or more power supplies. This condition is not ideal and can be avoided through careful design, but is generally not harmful. Attempting

to discharge the pre-bias is not advised as it may force high current though the leakage path. The EM2280 includes features to enable and disable into pre-biased output capacitors.

If the output capacitors are pre-biased when the EM2280 is enabled, start-up logic in the EM2280 ensures that the output does not pull down the pre-biased voltage and the  $t_{ON\_RISE}$  timing is preserved. Closed-loop stability is ensured during the entire start-up sequence under all pre-bias conditions.

The EM2280 also supports pre-biased off, in which the output voltage ramp down to a user-defined level (PMBus command: V<sub>OFF\_nom</sub>) rather than to zero. After receiving the disable command, via PMBus command or the CTRL pin, the EM2280 ramps down the output voltage to the predefined value. Once the value is reached, the output driver goes into a tristate mode to avoid excessive currents through the leakage path.

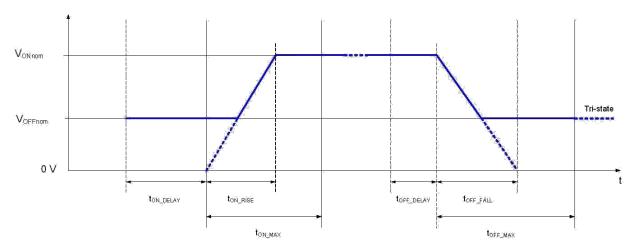

Figure 7: Power Sequencing With Non-Zero Off Voltage

#### **VOLTAGE TRACKING**

The EM2280 can control the output voltage based on the external voltage applied to the VTRACK pin, thus allowing sequencing of the output voltage from an external source. Pre-bias situations are also supported. The VTRACK pin voltage is a single-ended input referenced to analog ground. Tracking mode is disabled by default, but it can be enabled using the GUI software or via the manufacturer-specific PMBus command, MFR\_FEATURES\_CTRL (see Table 15).

If VTRACK is not intended to be used, tie the VTRACK pin low or leave it floating.

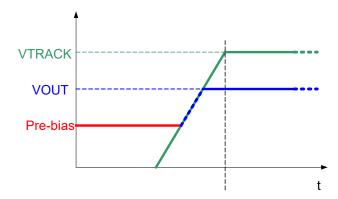

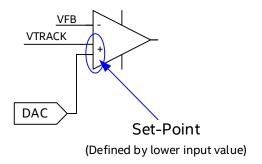

Figure 8: Power Sequencing Using VTRACK With Bias Voltage On VOUT

The set point voltage for the EM2280 is defined by the lower value of the  $V_{OUT}$  setting or an external voltage applied to the VTRACK pin. If the VTRACK voltage rises above the  $V_{OUT}$  set point voltage, then the final output

voltage will be limited by the  $V_{OUT}$  setting. If the tracking feature is enabled, but the VTRACK pin is tied low or floating, then the output will never start as the VTRACK pin input is always the lower value and will always be in control. Conversely, if tracking is enabled, but VTRACK is tied high, the output will start but will follow the  $V_{OUT}$  set point, not the VTRACK pin.

If tracking is used for sequencing, it is recommended that the VTRACK signal be kept greater than the  $V_{OUT}$  voltage. This ensures that the internal  $V_{OUT}$  set point is used as the final steady-state output voltage and accuracy is not a function of the externally applied VTRACK voltage. The tracking function will override a programmed pre-bias off level ( $V_{OFF\_nom}$ ).

**Figure 9: VTRACK Circuitry** 

The following figures demonstrate ratio-metric and simultaneous sequencing of the output voltage, which can be accomplished by applying an appropriate external voltage on the VTRACK pin. When using the VTRACK feature, the sequencing will be ratio-metric as shown in **Figure 12**, if an external resistor network is used at the VTRACK pin as shown in **Figure 10**. If no external resistors are used, the output sequence is simultaneous as shown in **Figure 1**.

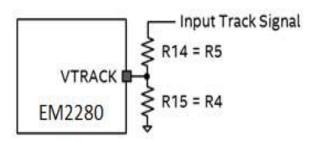

Figure 10: VTRACK Sense Circuitry with Resistor Divider

In the event that the tracking voltage applied to VTRACK is greater than 1.4V, then a  $2k\Omega$  resistor is required in series with the VTRACK pin to minimize leakage current as shown in Figure 1.

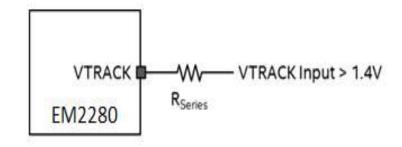

Figure 11: VTRACK Sense Circuitry (Input > 1.4V)

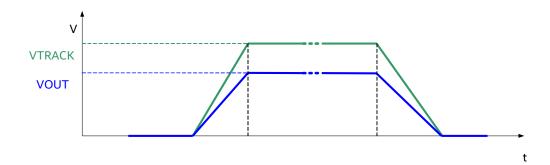

Figure 12: Ratiometric Sequencing Using VTRACK

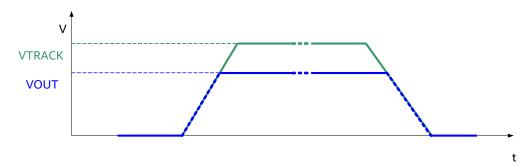

Figure 13: Simultaneous Sequencing Using VTRACK

## **CLOCK SYNCHRONIZATION**

The EM2280's PWM synchronization feature allows the user to synchronize the switching frequency of multiple devices. The SYNC pin can be configured as an input or an output.

The EM2280 SYNC functionality maybe configured as an input or an output using Intel's GUI software or via the manufacturer-specific PMBus command, MFR\_PIN\_CONFIG. The default configuration for synchronization control is OFF.

#### TEMPERATURE AND OUTPUT CURRENT MEASUREMENT

The EM2280 temperature sense block provides the device and the system with precision temperature information over a wide range of temperatures (-40°C to +150°C). The temperature sense block measures both the digital controller's temperature and a combination of both Power Train temperatures.

The EM2280 monitors output current by real-time, temperature compensated DCR current sensing across the inductor. This real-time current waveform is then digitally filtered and averaged for accurate telemetry, fault warning, and management.

Factory calibration has been performed for every EM2280 device to improve measurement accuracy over the full output current range. This allows the EM2280 to correct for DCR manufacturing variations.

For over-current protection, an unfiltered ADC is used in order to minimize delays in protecting the device. Because this measurement is unfiltered, the accuracy of the protection threshold is less than that of the average current reading.

#### PROTECTION AND FAULT RESPONSE

The EM2280 monitors various signals during operation in order to detect fault conditions. Measured and filtered signals are compared to a configurable set of warnings and fault thresholds. In typical usage, a warning sets a status flag, but does not trigger a response; whereas a fault sets a status flag and generates a response. The assertion of the SMBALERT signal can be configured to individual application requirements.

The EM2280 supports a number of different response types depending on the fault detected.

In the default configuration, the EM2280 responds to an over temperature event by ramping down  $V_{OUT}$  in a controlled manner at a slew rate defined by the  $T_{OFF\_FALL}$  value. This response type is termed "Soft-Off". The final state of the output signals depends on the value selected for  $V_{OFFnom}$ .

For all other faults the EM2280 will respond by immediately turning off both the top-side MOSFET and low-side MOSFET. This response type is termed "High-Impedance".

For each fault response, a delay and a retry setting can be configured. If the delay-to-fault value is set to non-zero, the EM2280 will not respond to a fault immediately. Instead it will delay the response by the configured value and then reassesses the signal. If the fault remains present during the delay time, the appropriate response will be triggered. If the fault is no longer present, the previous detection will be disregarded.

If the delay-to-retry value is set to non-zero, the EM2280 will not attempt to restart immediately after fault detection. Instead it will delay the restart by the configured value. If the fault is still present when attempting to restart, the appropriate response will be triggered. If the fault is no longer present, the previous detection will be disregarded. If the delay-to-fault is a non-zero value, then the delay-to-retry value will be a factor of 100 times greater than the delay-to-fault value.

The retry setting, i.e. the number of EM2280 restarts after a fault event, can be configured. This number can be between zero and six. A setting of seven represents infinite retry operation. This setting is commonly known as "Hiccup Mode."

#### WATCHDOG TIMER

General house-keeping operations are managed by an internal microcontroller (CPU). To ensure reliable CPU operation in all environments, a watchdog timer has been incorporated. The purpose of the watchdog timer is to reset the CPU as a last resort in the unlikely event of it entering an unknown state.

In the exception event of a reset the CPU will shut down the controller into a safe state and will then reload its memory, restarting the controller and output into its known good default operating condition.

## **PMBus Functionality**

#### INTRODUCTION

The EM2280 supports the PMBus protocol (version 1.2) to enable the use of configuration, monitoring, and fault management features during run-time.

The PMBus host controller is connected to the EM2280 via the PMBus pins (SDA, SCL). A dedicated SMBALERT pin is provided to notify the host that new status information is present.

The EM2280 supports packet correction (PEC) according to the PMBus™ specification.

The EM2280 supports clock stretching according to the SMBus specification.

The EM2280 communications utilizes clock stretching as required and this requires the PMBus master to support clock stretching. The EM2280 supports more than 60 PMBus commands in addition to several manufacturer specific commands related to output voltage, faults, telemetry, and more.

The EM2280 provides a PMBus set of synchronous communication lines, with serial clock input (SCL), serial data I/O (SDA), and serial alarm output (SALRT) pins.

The communication lines provide 1.8V I/O compatibility and open-drain outputs (SDA, SCL and SALRT). The communication lines require external pull-up resistors; typical applications require pull-up resistors on each end of the communication lines (typically values of 10 k $\Omega$  each), connected to VDD33 or an alternative termination voltage. Please refer to the PMBus specification (www.pmbus.org) for full details.

The EM2280 provides configurable behavior for the SALRT pin to allow users to determine which fault or warning conditions to communicate over the SALRT line. The default behavior of the controller ensures that any fault or warning results in the EM2280 SALRT pin going low; the alert behavior is enabled for all faults and warnings. You can deselect any of the faults or warnings so when one of these conditions occur, the SALRT pin is not pulled low.

The EM2280 provides a PMBus compliant power conversion control signal through input CTRL. You can configure input CTRL through the standard PMBus command ON\_OFF\_CONFIG.

By default configuration, the CTRL pin must be pulled high to enable operation and the PMBus command OPERATION is ignored. You can override this function with the ON OFF CONFIG PMBus command.

Remote measurement and reporting of telemetry information at the power supply level provides feedback on key parameters such as voltages, current levels, temperature, and energy, and allows reporting of information such as faults and warning flags. With this information, data is collected and analyzed while the power supply is in development, such as in the qualification or verification phases, or in the field, and system level interaction such as power capping is implemented. Several telemetry parameters are supported by standard PMBus commands.

The EM2280P supports PMBus output current telemetry through the READ\_IOUT command and reports the low-pass filtered, or DC, output current.

The standard PMBus command READ VOUT supports output voltage telemetry.

The standard PMBus command READ\_VIN supports input voltage telemetry.

The EM2280 supports temperature telemetry and reporting through standardized PMBus commands, READ\_TEMPERATURE\_1 is mapped to the summation of the Power Trains die temperatures and READ\_TEMPERATURE\_2 is mapped to the controller die temperature.

The EM2280 supports the LINEAR data format according to the PMBus specification. Note that in accordance with the PMBus specification, all commands related to the output voltage are subject to the VOUT\_MODE settings.

A detailed description of the supported PMBus commands supported by the EM2280 can be found in EM22xx Application Note – PMBus Commands Guide.

#### TIMING AND BUS SPECIFICATION

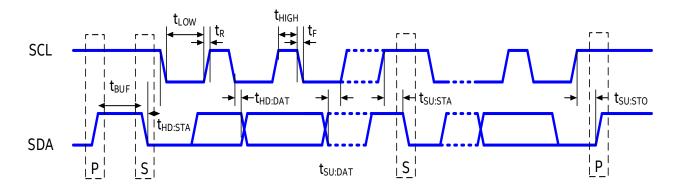

Figure 14: PMBus Timing Diagram

**Table 14: EM2280 PMBus Parameters** 

| Parameter                            | Symbol                | Conditions | Min | Тур | Max | Units |
|--------------------------------------|-----------------------|------------|-----|-----|-----|-------|
| PMBus operation frequency            | $f_{SMB}$             |            | 10  | 100 | 400 | kHz   |
| Bus free time between start and stop | t <sub>BUF</sub>      |            | 1.3 |     |     | μs    |
| Hold time after start condition      | t <sub>HD:STA</sub>   |            | 0.6 |     |     | μs    |
| Repeat start condition setup time    | t <sub>SU:STA</sub>   |            | 0.6 |     |     | μs    |
| Stop condition setup time            | t <sub>SU:STO</sub>   |            | 0.6 |     |     | μs    |
| Data hold time                       | t <sub>HD:DAT</sub>   |            | 300 |     |     | ns    |
| Data setup time                      | t <sub>SU:DAT</sub>   |            | 100 |     |     | ns    |
| Clock low time-out                   | t <sub>TIMEOUT</sub>  |            |     | 25  | 35  | ms    |
| Clock low period                     | t <sub>LOW</sub>      |            | 1.3 |     |     | μs    |

| Clock or data rise time              | t <sub>R</sub>        |            |     |     | 300 | ns    |

#### ADDRESS SELECTION VIA EXTERNAL RESISTORS

The PMBus protocol uses a 7-bit device address to identify different devices connected to the bus. This address can be selected via external resistors connected to the ADDRx pins.

The resistor values are sensed using the internal ADC during the initialization phase and the appropriate PMBus address is selected. Note that the respective circuitry is only active during the initialization phase; hence no DC voltage can be measured at the pins. The supported PMBus addresses and the values of the respective required resistors are listed in **Table 15.** 

**Table 15: Supported Resistor Values For PMBus Address Selection** 

| Address<br>(hex) | ADDR1<br>Ω | ADDR0<br>Ω | Address<br>(hex) | ADDR1<br>Ω | ADDR0<br>Ω | Address<br>(hex) | ADDR1<br>Ω | ADDR0<br>Ω |
|------------------|------------|------------|------------------|------------|------------|------------------|------------|------------|

Note: The gray-highlighted addresses with an asterick are reserved by the SMBus specification.

#### **PMBUS COMMANDS**

A detailed description of the PMBus commands supported by the EM2280 can be found in a separate document - *EM22xx PMBus Commands Guide*. Below, Table **16** lists of all supported PMBus commands.

**Table 16: List Of Supported PMBus Commands** 

| Command Code      | PMBus Parameter      | Description                        |
|-------------------|----------------------|------------------------------------|
| 01 <sub>HEX</sub> | OPERATION            | On/off command                     |
| 02 <sub>HEX</sub> | ON_OFF_CONFIG        | On/off configuration               |
| O3 <sub>HEX</sub> | CLEAR_FAULTS         | Clear status information           |
| 10 <sub>HEX</sub> | WRITE_PROTECT        | Protect against changes            |
| 11 <sub>HEX</sub> | STORE_DEFAULT_ALL    | Copy entire memory into OTP        |
| 12 <sub>HEX</sub> | RESTORE_DEFAULT_ALL  | Copy entire memory from OTP        |
| 13 <sub>HEX</sub> | STORE_DEFAULT_CODE   | Copy single parameter into OTP     |
| 14 <sub>HEX</sub> | RESTORE_DEFAULT_CODE | Copy single parameter from OTP     |
| 19 <sub>HEX</sub> | CAPABILITY           | PMBus Capabilities                 |
| 20 <sub>HEX</sub> | VOUT_MODE (Note 3)   | Exponent of the VOUT_COMMAND value |

| Command Code      | PMBus Parameter        | Description                                      |
|-------------------|------------------------|--|
| 21 <sub>HEX</sub> | VOUT_COMMAND           | Set output voltage                               |
|                   | <del>-</del>           |  |
| 22 <sub>HEX</sub> | VOUT_TRIM              | Apply a fixed offset voltage                     |
| 23 <sub>HEX</sub> | VOUT_CAL_OFFSET        | Apply a fixed offset voltage                     |
| 25 <sub>HEX</sub> | VOUT_MARGIN_HIGH       | Sets maximum value                               |
| 26 <sub>нех</sub> | VOUT_MARGIN_LOW        | Sets minimum value                               |
| 29 <sub>HEX</sub> | VOUT_SCALE_LOOP        | Scalar for output voltage divider                |
| 2A <sub>HEX</sub> | VOUT_SCALE_MONITOR     | Scalar for read-back with output voltage divider |
| 35 <sub>HEX</sub> | VIN_ON                 | Input voltage turn on threshold                  |
| 36 <sub>HEX</sub> | VIN_OFF                | Input voltage turn off threshold                 |
| 40 <sub>HEX</sub> | VOUT_OV_FAULT_LIMIT    | Over-voltage fault limit                         |
| 41 <sub>HEX</sub> | VOUT_OV_FAULT_RESPONSE | Over-voltage fault response                      |
| 42 <sub>HEX</sub> | VOUT_OV_WARN_LIMIT     | Over-voltage warning level                       |
| 43 <sub>HEX</sub> | VOUT_UV_WARN_LIMIT     | Under-voltage warning level                      |
| 44 <sub>HEX</sub> | VOUT_UV_FAULT_LIMIT    | Under-voltage fault level                        |
| 45 <sub>HEX</sub> | VOUT_UV_FAULT_RESPONSE | Under-voltage fault response                     |
| 4F <sub>HEX</sub> | OT_FAULT_LIMIT         | Power Train Over-temperature fault level         |
| 50 <sub>HEX</sub> | OT_FAULT_RESPONSE      | Power Train Over-temperature fault response      |
| 51 <sub>HEX</sub> | OT_WARN_LIMIT          | Power Train Over-temperature warning level       |
| 55 <sub>HEX</sub> | VIN_OV_FAULT_LIMIT     | Over-voltage fault limit                         |
| 56 <sub>нех</sub> | VIN_OV_FAULT_RESPONSE  | Over-voltage fault response                      |
| 57 <sub>HEX</sub> | VIN_OV_WARN_LIMIT      | Over-voltage warning level                       |
| 58 <sub>HEX</sub> | VIN_UV_WARN_LIMIT      | Under-voltage warning level                      |
| 59нех             | VIN_UV_FAULT_LIMIT     | Under-voltage fault level                        |
| 5A <sub>HEX</sub> | VIN_UV_FAULT_RESPONSE  | Under-voltage fault response                     |
| 5E <sub>HEX</sub> | POWER_GOOD_ON          | Power good on threshold                          |
| 5F <sub>HEX</sub> | POWER_GOOD_OFF         | Power good off threshold                         |
| 60нех             | TON_DELAY              | Turn-on delay                                    |
| 61 <sub>HEX</sub> | TON_RISE               | Turn-on rise time                                |

Note 3: VOUT\_ MODE is read only for the EM2280

#### **TYPICAL APPLICATION CIRCUIT**

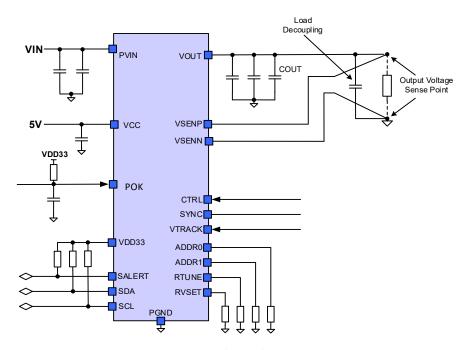

Figure 15: Typical Application Circuit

## **Layout Recommendations**

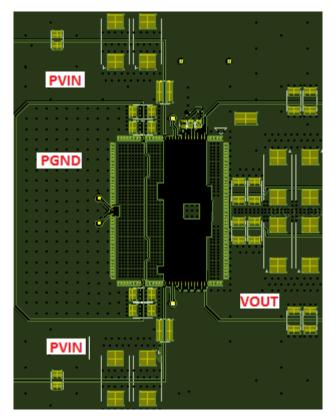

Figure 16: Top Layer Layout with Critical Components Only

**Recommendation 1:** It is good practice to minimize ground loops. Whenever possible the input and output loops should close to the same point, which is the ground of the EM2280 module. Module decoupling ceramic capacitors are to be placed as close as possible to the module in order to contain the switching noise in the smallest possible loops and to improve PVIN decoupling by minimizing the series parasitic inductance of the PVIN traces. For achieving this goal, it helps to place decoupling capacitors on the same side as the module since VIAs are generally more inductive, thus reducing the effectiveness of the decoupling. Of course, bulk and load high frequency decoupling should be placed closer to the load.

**Recommendation 2:** It is good practice to place the other small components needed by the EM2280 on the opposite side of the board, in order to avoid cutting the power planes on the module side. Since the EM2280's heat is evacuated mostly through the PCB, this will also help with heat dissipation; wide copper planes under the module can also help with cooling. The PVIN copper plane should not be neglected as it helps spread the heat from the high side FET.

**Recommendation 3**: It is recommended that at least below the EM2280 module, the next layers to the surface (2 and n-1) be solid ground planes, which provides shielding and lower the ground impedance at the module level, in order to reduce the ground impedance and reduce noise injection.

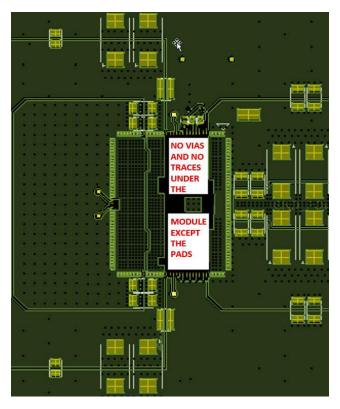

Figure 17: VIAs in The Power Pads

**Recommendation 4**: In order to better spread the current and the heat through the inner layers, arrays of VIAs should be placed in the power pads. 10mils diameter is a good size for the plated in-pad VIAs. It is critical that through VIAs should not be placed by any means elsewhere under the module; the non-pad area around AGND is VIA keep out area.

**Recommendation 5**: All other signal and LDO decoupling capacitors should be placed as close as possible to the terminal they are decoupling.

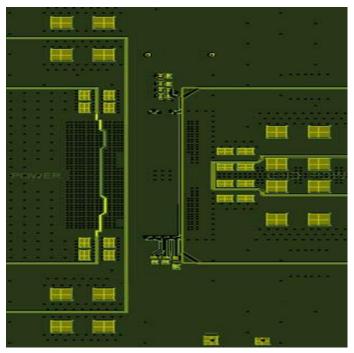

Figure 18: Backside Decoupling

All Signal Decoupling Go to The Bottom AGND Plane and Get Connected to The EM2280 Module AGND Through the AGND In-PAD VIAs (Again, No Other VIAs Are Allowed In That Area)

**Recommendation 6:** Differential remote sense should be routed as much as possible as a differential pair, on an inner layer, preferably shielded by a ground plane.

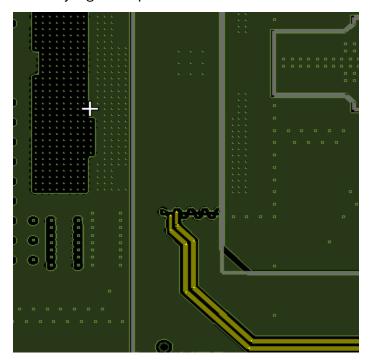

Figure 19: Remote Sense Routing on An Inner Layer (Highlighted, Yellow)

**Recommendation 7**: If the design allows it, stitching VIAs can be used on the power planes, close to the module in order to help with cooling. This is a thermal consideration and does not matter much for the electrical design.

## **Package Bottom Side View**

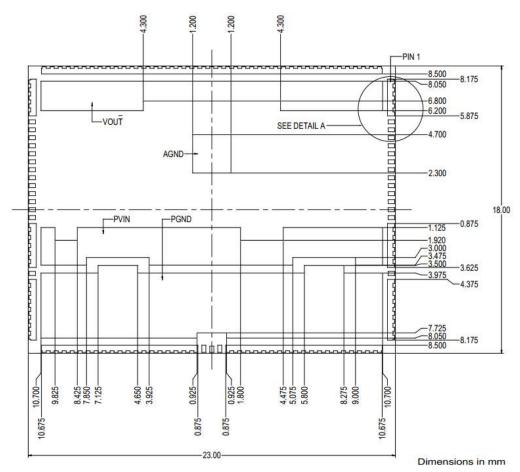

Figure 7: Package Bottom side (Bottom View)

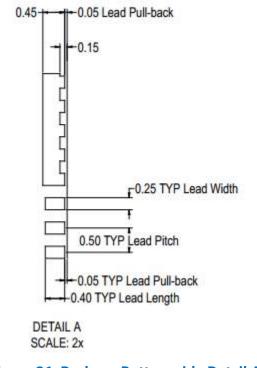

Figure 21: Package Bottom side Detail A

## **Recommended PCB Footprint**

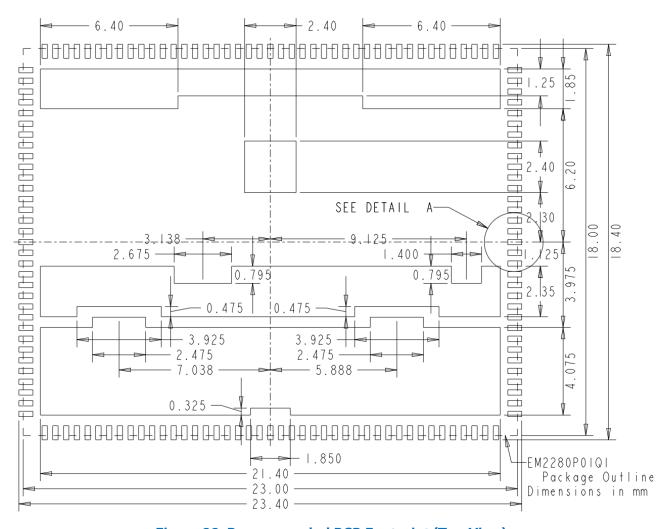

Figure 22: Recommended PCB Footprint (Top View)

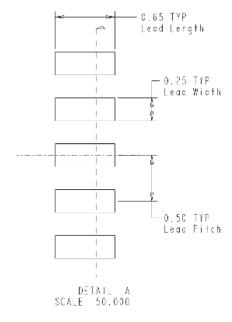

Figure 23: Recommended PCB Footprint Detail A

## **Recommended Solder Stencil Aperture**

The solder stencil for each pad under the device is recommended to be up to 30% of the total pad size.

The aperture dimensions are based on a 4mil stencil thickness.
