

**ABSTRACT**

This user's guide describes the characteristics, operation, and use of the PGA2500EVMV2, a refreshed evaluation module (EVM) that is compatible with the PGA2500 on a modern operating system. This document includes the schematic, printed circuit board (PCB) layout, and Bill Of Materials (BOM). Throughout this document the terms evaluation board, evaluation module, and EVM are synonymous with the universal PGA2500EVMV2.

1 Product Overview

The PGA2500 is a digitally-controlled, microphone preamplifier integrated circuit designed for amplifying the output of dynamic and condenser microphones and driving high-performance audio analog-to-digital (A/D) converters. Figure 1-1 shows a functional block diagram of the PGA2500.

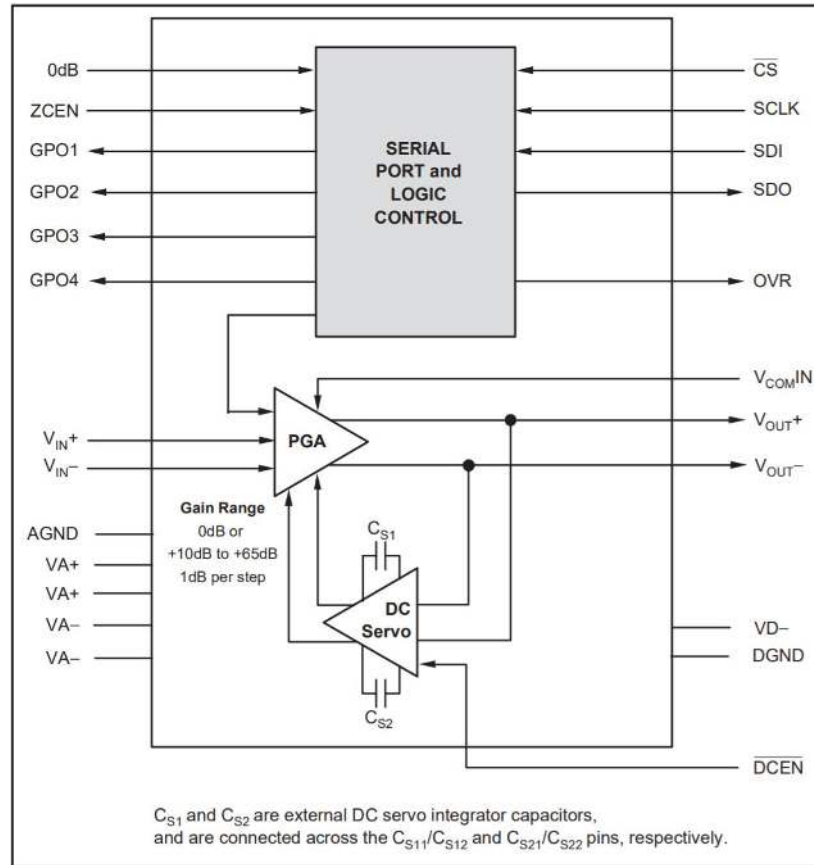

Figure 1-1. PGA2500 Functional Block Diagram

The analog input to the preamplifier is provided differentially at the VIN+ and VIN- inputs (pins 27 and 26, respectively). The programmable gain amplifier can be programmed to either pass through the signal at unity gain, or apply 10 dB to 65 dB of gain to the input signal. The gain of the amplifier is adjustable over the full 10 dB to 65 dB range in 1-dB steps. The differential output of the PGA2500 is made available at VOUT+ and VOUT- (pins 17 and 16, respectively). Gain is controlled using a MSP430F5529 microcontroller and PGA2500EVMV2 Graphical User Interface (GUI), which can be accessed [here](#). The microcontroller and GUI are used to program the PGA2500 gain and support functions, see Figure 1-2.

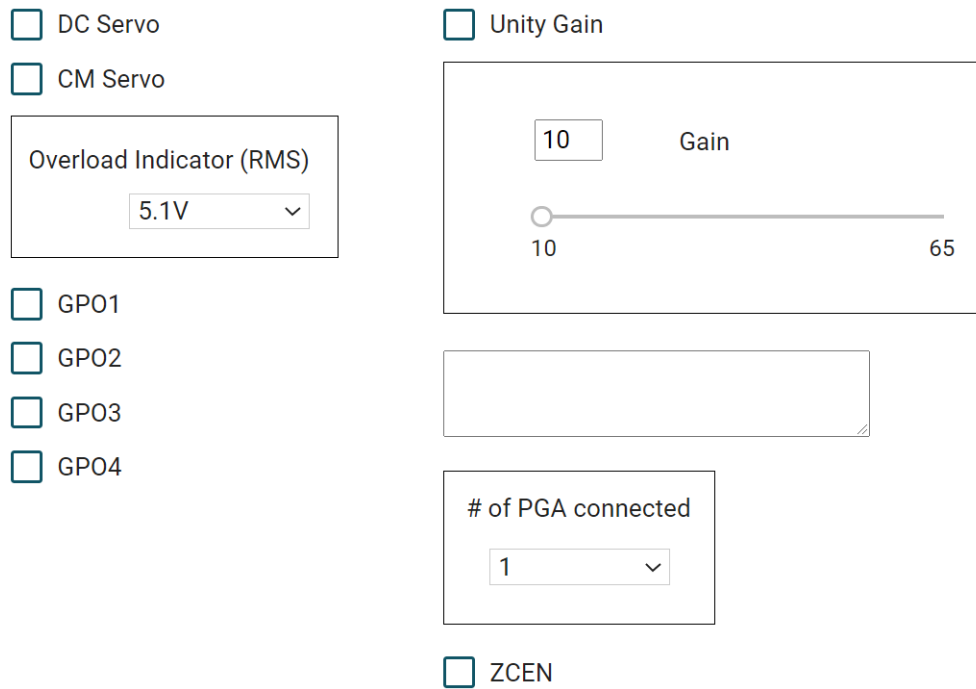

Figure 1-2. PGA2500EVMV2 GUI

A 16-bit control word is utilized to program these functions; see [Figure 1-3](#).

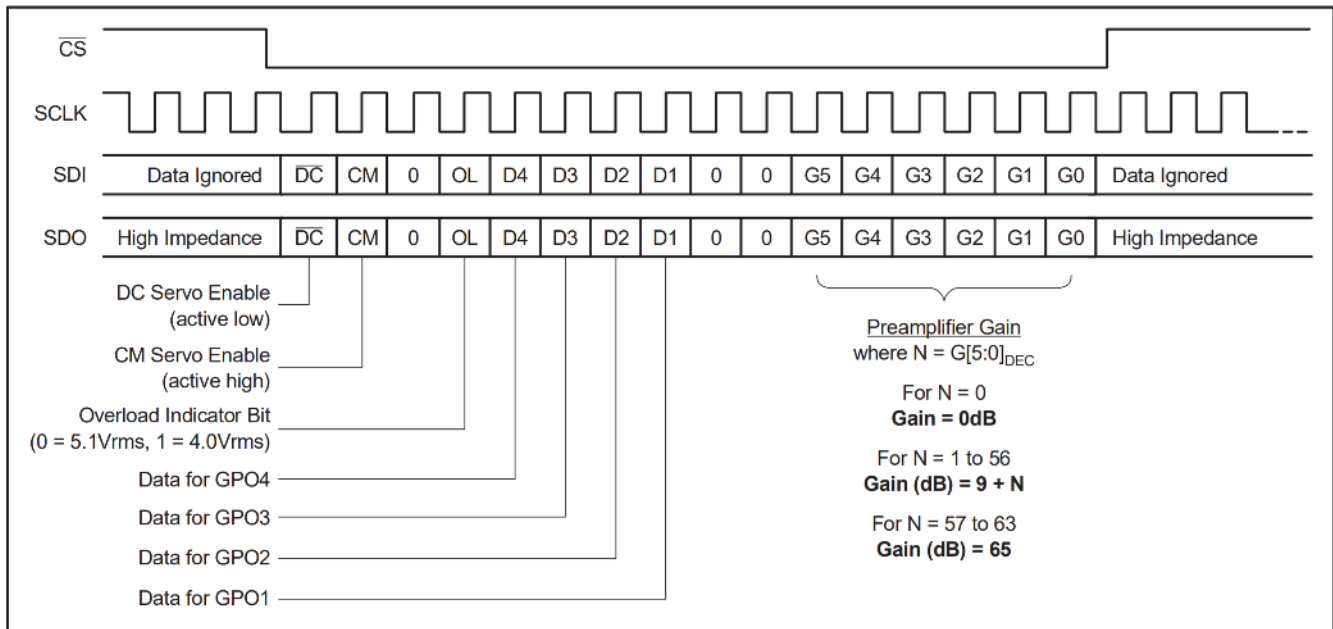

Figure 1-3. PGA2500 16-bit Control

The differential analog output of the PGA2500 is constantly monitored by a DC servo amplifier loop. The purpose of the servo loop is to minimize the DC offset voltage present at the analog outputs by feeding back an error signal to the input stage of the programmable gain amplifier. The error signal is then used to correct the offset. The DC servo may be enabled by checking the *DC Servo* checkbox in the GUI. To disable this function, leave the *DC Servo* checkbox in the GUI unchecked.

Two external capacitors are required for the DC servo function, with one capacitor connected between CS11 and CS12 (pins 24 and 23), and the second capacitor connected between CS21 and CS22 (pins 22 and 21). Capacitor values up to 4.7 μ F may be utilized. However, larger valued capacitors will result in longer

settling times for the DC servo loop. A value of 1 μ F is recommended for use in most microphone preamplifier applications.

The PGA2500 includes a common-mode servo function. This function is enabled and disabled using the CM bit in the serial control word, as shown in [Figure 1-3](#), or by checking the *CM Servo* checkbox in the GUI. When enabled, the servo provides common-mode negative feedback at the input differential pair, resulting in very low common-mode input impedance. The differential input impedance is not affected by this feedback. This function is useful when the source is floating, or has a high common-mode output impedance. In this case, the only connection between the source and the ground will be through the PGA2500 preamplifier input resistance.

In this case, input common-mode parasitic current is determined by high output impedance of the source, not by input impedance of the amplifier. Therefore, input common-mode interference can be reduced by lowering the common-mode input impedance while not increasing the input common-mode current. Increasing common-mode current degrades common-mode rejection. Using the common-mode servo, overall common-mode rejection can be improved by suppressing low and medium frequency common-mode interference.

The common-mode servo function is designed to operate with a total common mode input capacitance (including the microphone cable capacitance) of up to 10 nF. Beyond this limit, stable servo operation is not ensured.

The common-mode voltage control input, named VCOMIN (pin 25), allows the PGA2500 output and input to be DC biased to a common-mode voltage between 0 V and +2.5 V. This allows for a DC-coupled interface between the PGA2500 preamplifier output and the inputs of common single-supply audio A/D converters.

A dedicated 0-dB input (pin 8) is provided so that the gain of the PGA2500 may be forced to unity. Check the *Unity Gain* checkbox in the GUI to activate this function.

The zero-crossing control input, named ZCEN (pin 9), is provided for enabling and disabling the internal zero-crossing detector function. Forcing the ZCEN input high enables the function, check the *ZCEN* checkbox in the GUI to activate this function. Zero-crossing detection is used to force gain changes on zero crossings of the analog input signal. This limits the glitch energy associated with the switched gain network, thereby minimizing audible artifacts at the preamplifier output. Since zero-crossing detection can add some delay when performing gain changes (up to 16 ms maximum for a detector timeout event), there may be cases where the user may wish to disable the function. Forcing the ZCEN input low (unchecking the checkbox in the GUI) disables zero-crossing detection, with gain changes occurring immediately when programmed.

An overflow indicator output, OVR, is provided at pin 5. The OVR pin is an active high, CMOS-logic-level output. The overflow output is forced high when the preamplifier output voltage exceeds one of two preset thresholds. The threshold is programmed through the graphical user interface using the *Overload Indicator (RMS)* drop-down menu. When this Overload Indicator option is set to "5.1V" RMS differential, that is approximately -1 dB below the specified output voltage range. When the Overload Indicator option is set to "4.0V" RMS differential, that is approximately -3 dB below the specified output voltage range.

The PGA2500 includes four general-purpose programmable digital outputs, named GPO1 through GPO4 (pins 1 through 4, respectively), which are controlled via the GUI as checkboxes. All four pins are CMOS-logic-level outputs. These pins may be used to control relay drivers or switches used for external preamplifier functions, including input pads, filtering, polarity reversal, or phantom power.

2 Features

The PGA2500EVMV2 provides a convenient platform for evaluating the performance and features of the PGA2500 product. Key EVM features include the following:

- Accepts either XLR or TRS balanced input connections
- Configurable front-end circuit options for prototyping pads and filters
- XLR and TRS balanced output with flexible output loading options
- LED indicators for GPOs and the over range output
- Common-mode voltage input (VCOMIN) terminal
- Includes applications software which is compatible with most personal computers that have a built-in USB port
- Requires +5-V and -5-V analog supplies, as well as a +5-V digital supply
 - The user may leave the +5-V digital supply (VCC) unconnected if using the MSP-EXP430F5529LP

3 Getting Started

This section provides information regarding PGA2500EVMV2 handling and unpacking, as well as the absolute operating conditions.

3.1 Electrostatic Discharge Warning

Many of the components on the PGA2500EVMV2 are susceptible to damage by electrostatic discharge (ESD). Customers are advised to observe proper ESD handling precautions when unpacking and handling the EVM. Failure to observe ESD handling procedures may result in damage to the EVM components.

3.2 Unpacking the EVM

In addition to the PGA2500EVMV2 evaluation module board, order and unpack the MSP-EXP430F5529LP, [MSP430F5529 USB LaunchPad development kit](#). Plug in the MSP430 microcontroller on top of the PGA2500EVMV2, see [Figure 3-1](#).

Figure 3-1. PGA2500EVMV2 With MSP430™ Microcontroller Connected

3.3 Absolute Operating Conditions Warning

The user should be aware of the absolute maximum operating conditions for the evaluation module. [Table 3-1](#) summarizes the critical data points.

Table 3-1. PGA2500EVMV2 Absolute Maximum Operating Conditions

Parameter	Package Reference
Power-Supply Voltages	+5.5 V DC Maximum
VA+	-5.5 V DC Maximum
VA-	-0.3 V DC Minimum to (VA+) + 0.3 V DC
VCOM	Maximum
VCC	+5.5 V DC Maximum
Phantom Power	+50 V DC Maximum
Microphone Input (J3), XLR, or TRS Maximum Input Voltage, Differential	20 V _{PP} (or 7 V RMS) Maximum
Preamplifier Output (J6) Maximum Output Voltage, Differential	17.5 V _{PP} (or 6.2 V RMS) Maximum

4 Setup Guide

This section provides descriptions of the hardware components that make up the PGA2500EVMV2. In addition, configuration information for power supplies, analog input and output connections, switches, and jumpers are provided.

4.1 Analog and Digital Power Supplies

All analog and digital power supplies are connected through terminal block J2, see [Figure 4-1](#). Recommended power-supply connections are described in the following:

- +VA and -VA are +5 V and -5 V
- Connect EGND to earth or chassis ground of the power supply
- Connect GND to common ground
- Leave VCC unconnected if using the MSP-EXP430F5529LP

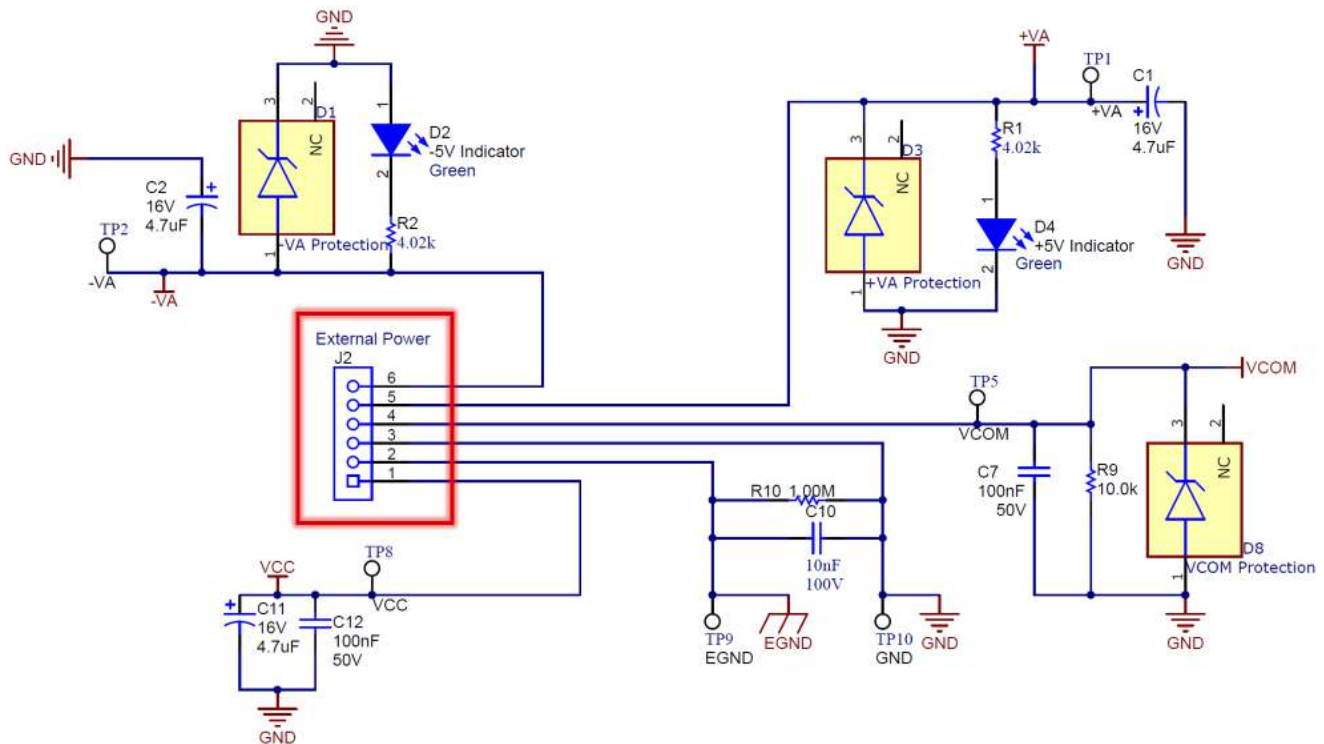

Figure 4-1. Power Terminal Block J2 Schematic

The PGA2500EVMV2 requires two analog supplies and one digital power supply. The analog supplies are VA+ and VA-, respectively. VA+ is typically set to +5.0 V DC, while VA- is typically set to -5.0 V DC. The analog supplies power the PGA2500 microphone preamplifier integrated circuit. The digital power supply, VCC, is left unconnected if using the MSP-EXP430F5529LP.

An optional third analog power supply may be utilized for the PGA2500 common-mode DC voltage input, VCOMIN (pin 25). VCOMIN allows the PGA2500 output and input to be DC biased to a common-mode voltage between 0 and +2.5 V and is connected through terminal block J2. The common-mode voltage biases both the output and input terminals of the PGA2500, with the output pins being biased to the VCOMIN voltage level and the input pins being biased to approximately VCOMIN - 0.65 V.

The GND terminal of connector J2 serves as the common ground connection for both the analog and digital sections of the PGA2500EVMV2. The EGND (earth ground) terminal should be connected to the earth or chassis ground of the power supply. The common ground (GND) and earth ground (EGND) are connected to one another using a 0.1- μ F capacitor (C10).

4.2 Microphone Input

Dynamic and condenser microphones or audio test equipment are connected to the PGA2500EVMV2 input through combo connector J3. The combo connector combines both a 3-pin female XLR and a 1/4-inch TRS jack for connecting to microphones and test signal sources. Both the XLR and TRS jacks are wired for a balanced input. Figure 4-2 illustrates the combo connector pin configuration for the PGA2500EVMV2.

Figure 4-2. Microphone Input Connector Configuration

4.3 Phantom Power Connections

The PGA2500EVMV2 supports connection of a phantom power source across the inputs of the preamplifier using terminal block J1. The voltage source is connected to the hot (+) and cold (-) sides of the preamplifier input through 6.81-k Ω resistors. Phantom power may be operated at voltages up to +50 V DC.

Phantom power is required for condenser microphones. When using a condenser microphone requiring a phantom power source, short terminals 1 and 2 of jumper JMP1, and leave terminals 3 and 4 open. It is important to note that when using a phantom power source, connect the microphone and cable before turning on phantom power. In addition, phantom power should be turned off before disconnecting the microphone or cable. Making or breaking the input connection with +48 V may cause large transient spikes which could damage the PGA2500 or anything connected to the output. When using a dynamic microphone, terminals 3 and 4 of jumper J3 should be shorted, while terminals 1 and 2 remain open.

4.4 DC Blocking Capacitors

Capacitors C4 and C9 are utilized as DC blocking capacitors. They provide AC-coupling to the microphone input, as well as blocking the phantom voltage from reaching the PGA2500 input terminals when using a condenser microphone. The blocking capacitors are selected to not degrade the dynamic performance of the PGA2500. The capacitors shown in the [Bill of Materials](#) (see [Table 5-1](#)) are installed by default at the factory. If using an alternative capacitor, use components rated for 50 V minimum, with 63 V or higher recommended for long-term reliability.

4.5 Protection Network

Resistors R4 and R14, along with Schottky diodes D5, D6, D7 and D9, provide input protection for the PGA2500 preamplifier when using phantom power, or when the input voltage exceeds the VA+ or VA- power supplies by more than 350 mV (the approximate turn-on voltage of the Schottky diodes).

A common fault condition is for either the hot (+) or cold (-) input of the preamplifier to be shorted to ground. With phantom voltage applied, this causes the blocking capacitors to discharge, with a large surge current presented at the PGA2500 input pins. Without the protection network, the PGA2500 would be permanently damaged by the surge current, which can reach several amperes in peak magnitude.

The Schottky diodes are forced into conduction during this fault condition, steering most of the charge away from the PGA2500 device and towards the power supplies. The series resistors can be set to a value that will help limit the input current, although care must be taken to avoid adding too much resistance, since the added noise can degrade the overall performance of the preamplifier. The Schottky diodes add a nonlinear capacitance to the input circuit, which can result in additional distortion. However, with the relatively small input voltage swing present when the preamplifier is set to gains between 10 dB and 65 dB, the effect on the THD+N of the PGA2500 is small or negligible. For unity-gain applications, where the voltage swing may become large enough in magnitude to transition over a greater portion of the diodes nonlinear capacitance, the THD+N ratio may degrade by as much as 3 dB from the published typical performance specifications.

4.6 Configurable Input Circuitry

The configurable portion of the input circuit includes R5, R6, R8, R13, R15, R16, Cc1, and Cc2. These components support prototyping of additional circuitry, such as pads and filters. During assembly at the factory, resistors R8 and R13 are not installed, while R5, R6, R15, R16, Cc1, and Cc2 are replaced by 0- Ω shunt resistors.

4.7 Configurable Output Circuitry and Preamp Output Connector

The configurable portion of the output circuit includes R17, R18, R19, R20, R21, C13, C14, and C15. These components support prototyping of additional circuitry, such as pads and filters, as well as emulation of various loading conditions. During assembly at the factory, resistors R18 and R19 are replaced by 0- Ω shunt resistors. Resistors R17, R20, and R21, as well as capacitors C13 through C15, are not installed. The differential preamplifier output is provided at connector J4, which is a 3-pin male XLR connector, or at connector J6, which is a 1/4-inch TRS connector.

5 Schematic, PCB Layout, and Bill of Materials

This section provides the electrical schematic and physical PCB layout information for the PGA2500EVMV2. The [Bill of Materials](#) is included for component reference.

5.1 Schematic

The complete electrical schematic for the PGA2500EVMV2 is shown in [Figure 5-1](#). Refer to the [Bill of Materials](#) in [Table 5-1](#) for descriptions of components shown in the schematic.

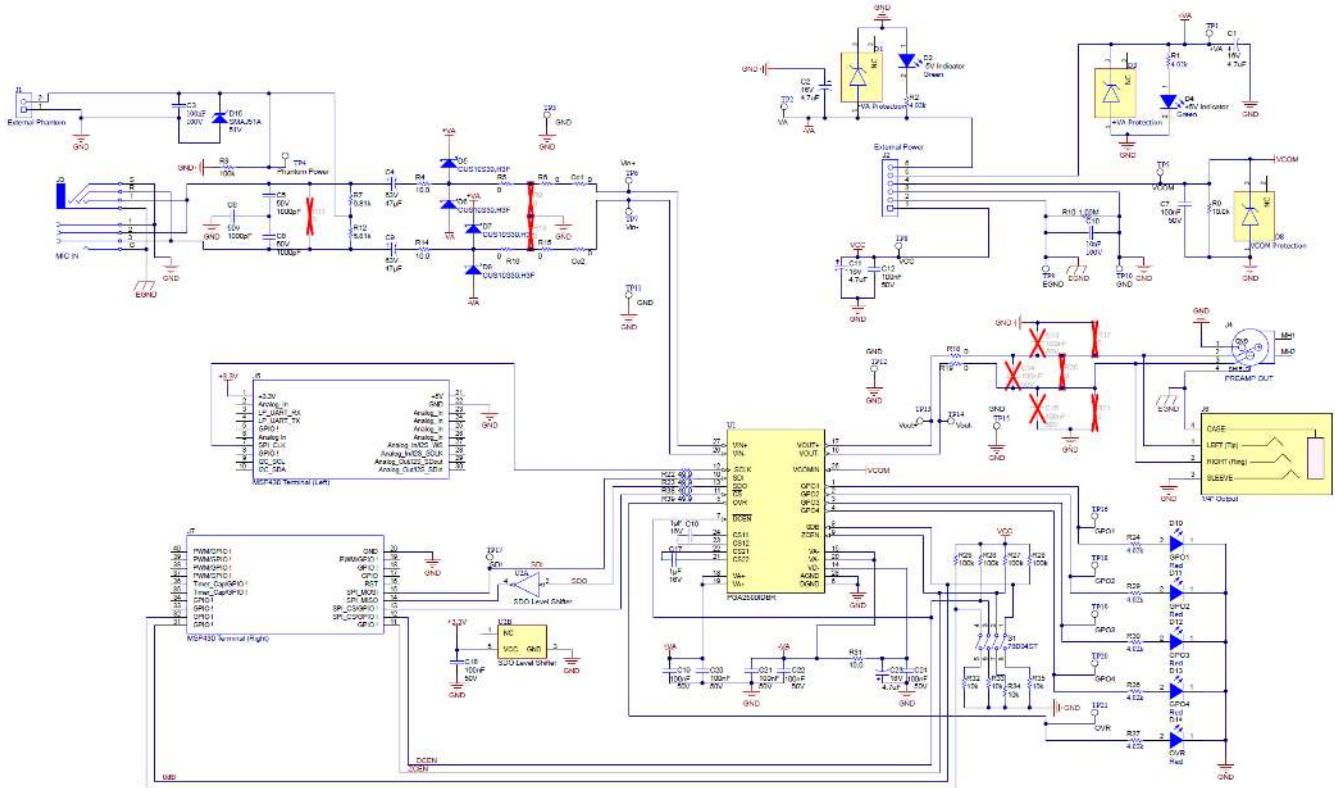

Figure 5-1. PGA2500EVMV2 Schematic

5.2 PCB Layout

The PGA2500EVMV2 is a four-layer printed circuit board using both through-hole and surface-mount components.

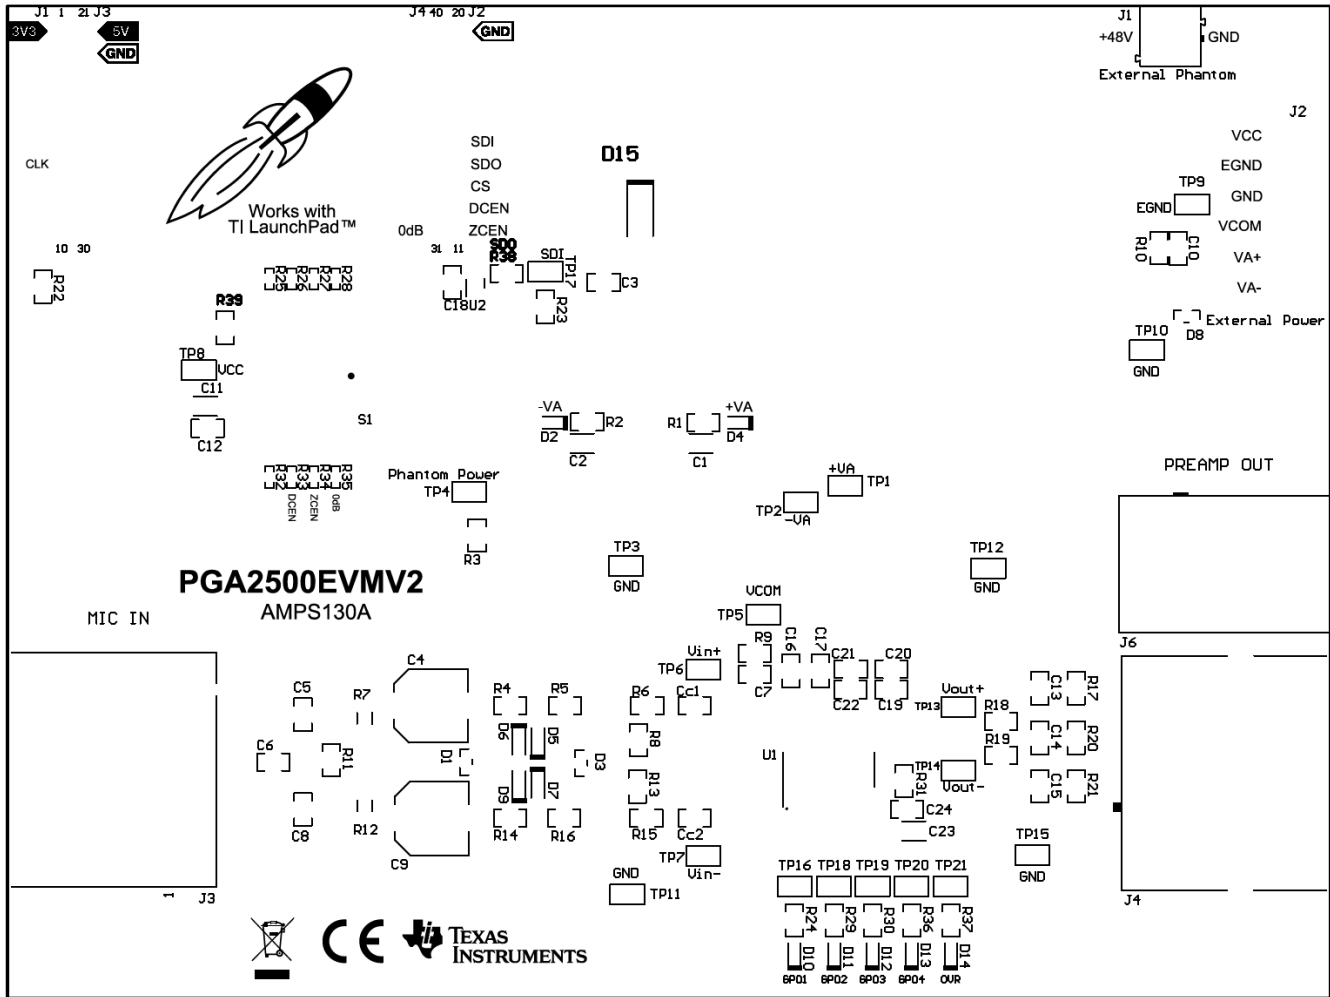

Figure 5-2. PGA2500EVMV2 Top Overlay

Figure 5-3. PGA2500EVMV2 Top Layer

Figure 5-4. PGA2500EVMV2 Bottom Layer

5.3 Bill of Materials

Table 5-1 lists the complete bill of materials for the PGA2500EVMV2. Data for each component is available from the corresponding manufacturer's web site.

6 Software Operation

This section provides instructions for using the PGA2500EVMV2 application software and using the software to control the PGA2500 gain and support functions.

6.1 Applications Software Overview

The applications software supplied with the PGA2500EVMV2 allows the user to control the board via an online GUI, found [here](#). All programmable functions are supported.

6.2 Using the GUI

Connect the MSP-EXP430F5529LP to the PGA2500EVMV2 board. Connect this to the computer via the USB cable and launch the GUI to automatically flash the microcontroller and adjust all programmable functions. Successful flash can be visually confirmed by GPO LEDs flashing in sequence. Manually set the COM port in the GUI composer to the COM port titled *Microsoft* after the successful flash by clicking File → Options → Serial Port.

When successfully connected to the microcontroller via serial COM port, the MSP430 will acknowledge successful GUI control actions by printing to this textbox, shown in [Figure 6-1](#):

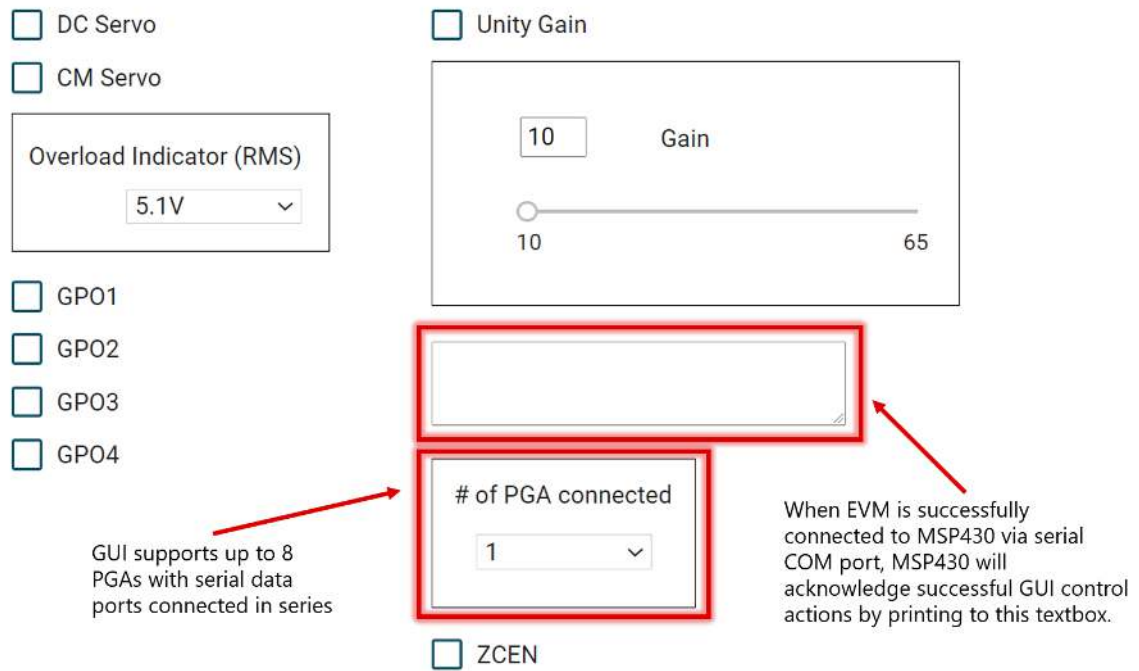

Figure 6-1. PGA2500EVMV2 GUI With Programmable Functions
