TEXAS INSTRUMENTS

TMP144 Low-Power, Digital Temperature Sensor With SMAART Wire™ / UART Interface

1 Features

- Multiple Device Access (MDA):
  - Global read/write operations
- SMAART Wire™ / UART interface
- Resolution: 12-bit or 0.0625 °C
- ±1 °C maximum (–10 °C to +100 °C)
- ±2 °C maximum (–40 °C to +125 °C)
- Low quiescent current:
  - 3-µA active I_Q at 0.25 Hz
  - 0.6-µA shutdown
- Supply range: 1.4 V to 3.6 V
- Push-pull digital output
- Package:
  - 0.76 mm × 0.96 mm, 150-µm maximum height, 4-ball YMT (DSBGA)
  - 0.76 mm × 0.96 mm, 625-µm maximum height, 4-ball YFF (DSBGA)

2 Applications

- Handsets
- Smartphones
- Tablets
- LED Backlighting
- HDTVs
- Enterprise Servers
- Notebooks
- Medical

3 Description

The TMP144 digital output temperature sensor can read temperatures to a resolution of 0.0625 °C.

The device has a SMAART Wire™ / UART interface that supports daisy-chain configurations. The interface also supports Multiple Device Access (MDA) commands that let the host communicate with multiple devices on the bus simultaneously. MDA commands are used as an alternative to sending individual commands to each device on the bus. Up to 16 TMP144 devices can be attached together serially and can be read by the host computer.

The TMP144 device is designed for space-constrained, power-sensitive applications with multiple temperature measurement zones that must be monitored. The device is specified for operation over a temperature range of –40 °C to 125 °C and is available in two different 4-ball, low-height wafer chip-scale package (DSBGA) options. The YMT package of the device has a height of 150 µm, which is 40% thinner than a 0201 resistor. The thinner YMT package can be placed under heat-dissipating components on the system for better accuracy and faster thermal response times.

Device Information[1]

PART NUMBER	PACKAGE	BODY SIZE (NOM)
TMP144	YFF DSBGA (4)	0.76 mm x 0.96 mm
	YMT DSBGA (4)	0.76 mm x 0.96 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.
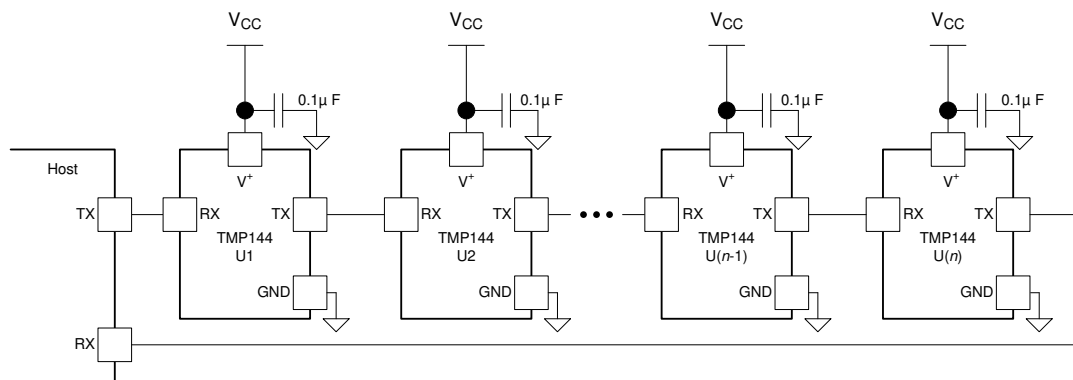

Up to 16 TMP144 devices can be configured as a daisy-chain. (See *Device Nomenclature*)

6 Specifications

6.1 Absolute Maximum Ratings

Over free-air temperature range unless otherwise noted[1]

		MIN	MAX	UNIT
Supply voltage	V+	−0.3	4.0	V
Input voltage	RX	−0.3	(V+) + 0.3 and ≤ 4	V
I/O current	TX		±15	mA
Operating junction temperature, T_J		−55	150	°C
Storage temperature, T_{stg}		−60	150	°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

			VALUE	UNIT
$V_{(ESD)}$	Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001[1]	±2000	V
		Charged-device model (CDM), per JEDEC specification JESD22-C101[2]	±1000	V

(1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

		MIN	NOM	MAX	UNIT
V+	Supply voltage	1.4	3.3	3.6	V
$V_{I/O}$	RX	0		V+	V
T_A	Operating ambient temperature	-40		125	°C

6.4 Thermal Information

7 Detailed Description

7.1 Overview

The TMP144 is a digital output temperature sensor in a wafer chip-scale package (WCSP) that is designed for thermal management and thermal profiling. The TMP144 includes a SMAART Wire™ / UART interface that can communicate in a daisy-chain loop with up to 16 devices on a single bus. The interface requires two pins from the host: the first device in the daisy-chain receives data from the host and the last device in the daisy-chain returns data to the host, closing the loop. In addition, the TMP144 can do multiple device access (MDA) commands that allow multiple TMP144 devices to respond to a single global bus command. MDA commands reduce communication time and power in a bus that contains multiple TMP144 devices. The operation of TMP144, is specified over a temperature range of –40 °C to 125 °C.

The TMP144 can also configure the bus in a transparent mode, where the input from the host is sent directly to the next device in the chain without delay. Additionally, the TMP144 can disconnect the chain and create a serial communication controlled by each TMP144 on the bus, thereby allowing each device to have configurable addressing and interrupt capabilities. The input pin, RX, is a high-impedance node. The output pin, TX, has an internal push-pull output stage that can drive the host to GND or V+.

After an initialization sequence, each device on the bus is programmed with its own unique interface address based upon its position in the chain, that allows it to respond to its own address. The devices can also respond to general commands that permit the user to read or write to all devices on the bus without the need to send individual addresses and commands to each device.

The temperature sensor in the TMP144 is the chip itself. Thermal paths run through the package bumps as well as the package. The lower thermal resistance of metal and the low height of the devices, causes the bumps and the topside to provide the dominant thermal paths to the sensing element on the device. To maintain accuracy in applications that require air or surface temperature measurement, care should be taken to isolate the package from ambient air temperature. A thermally-conductive adhesive can help to achieve accurate surface temperature measurement.

7.2 Functional Block Diagram

Product Folder Links: *TMP144*
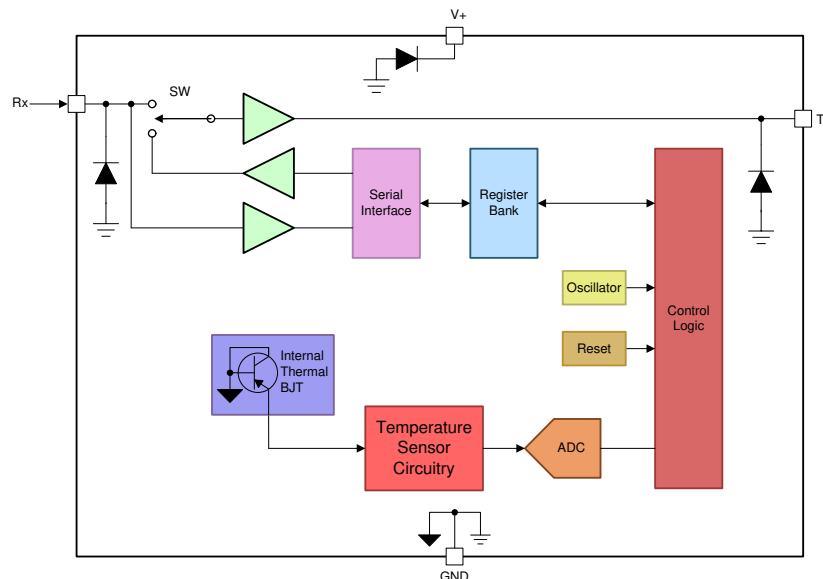

7.3 Feature Description

7.3.1 Power Up

After power-up or general-call reset, the TMP144 immediately starts a conversion as shown in Figure 7-1. The active conversion time (t_{ACT}) of the device is 26 ms (typical) and the first result is available after the conversion is complete in the temperature result register.

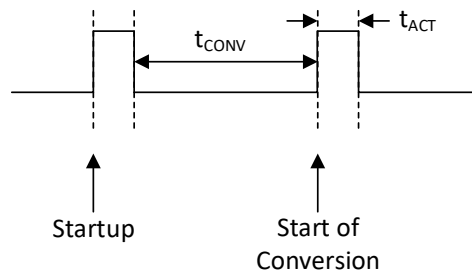

Figure 7-1. Conversion Start

7.3.2 Digital Temperature Output

The TMP144 by default provides a 12-bit digital output for each temperature conversion, which is stored in the temperature result register. The host application needs to read two bytes to obtain the data. Additionally, the application may program the ETM bit in the configuration register to get a 13-bit digital output. Table 7-1 summarizes the temperature output format. One LSB equals 0.0625 °C resolution.

Table 7-1. Temperature Data Format

TEMPERATURE (°C)	DIGITAL OUTPUT (ETM = 0)		DIGITAL OUTPUT (ETM = 1)	
	BINARY (T11-T0)	HEX	BINARY (T12-T0)	HEX
+150	0111 1111 1111	7FF	0 1001 0110 0000	0960
+127.9375	0111 1111 1111	7FF	0 0111 1111 1111	07FF
+125	0111 1101 0000	7D0	0 0111 1101 0000	07D0
+100	0110 0100 0000	640	0 0110 0100 0000	0640

0	0000 0000 0000	000	0 0000 0000 0000	0000
-0.0625	1111 1111 1111	FFF	1 1111 1111 1111	1FFF
-25	1110 0111 0000	E70	1 1110 0111 0000	1E70
-40	1101 1000 0000	D80	1 1101 1000 0000	1D80

7.3.3 Timeout Function

A timeout mechanism is implemented on the TMP144 to allow for re-synchronization of the SMAART Wire™ interface if synchronization between the host and the TMP144 is lost for 28 ms (typical). If the timeout period expires between the calibration byte and the command byte, between the command byte and a data byte, or between any data bytes, the TMP144 resets the SMAART Wire™ interface circuitry and waits for the baud rate calibration command to restart. Every time a byte is transmitted on the SMAART Wire™ interface, this timeout period restarts.

7.4 Device Functional Modes

7.4.1 Continuous Conversion Mode

When the TMP144 is in Continuous Conversion mode (M1 = 1), continuous conversions are performed at a rate determined by the conversion rate bits, CR[1:0], in the configuration register. The TMP144 performs a single conversion, then powers down and waits for the appropriate delay set by CR[1:0].

7.4.2 Shutdown Mode

Shutdown mode saves maximum power by shutting down all device circuitry other than the serial interface, reducing the current consumption to typically less than 0.5 µA. Shutdown mode is enabled when bits M[1:0] in the configuration register are set as "00". If there is an active conversion ongoing, the device completes the ongoing conversion, updates the temperature result register and shuts down.

7.4.3 One-Shot Mode

The TMP144 features a One-Shot Temperature Measurement mode. When the device is in Shutdown mode, writing 01 to bits M[1:0] in the configuration register, starts a single temperature conversion. During the conversion, the bits M[1:0] read 01. The device returns to the shutdown state at the completion of the single conversion. After the conversion, bits M[1:0] read 00. This feature is useful for reducing power consumption in the TMP144 when continuous temperature monitoring is not required.

As a result of the short conversion time, the TMP144 can achieve a higher conversion rate. A single conversion typically takes 26 ms and an individual read can take place in less than 300 µs. When using One-Shot mode, 30 or more conversions per second are possible.

7.4.4 Extended Temperature Mode

At power on, the TMP144 operates with a 12-bit temperature output. However, the TMP144 can be programmed to operate in Extended Temperature mode, by setting the ETM bit in the configuration register as '1'. When operating in extended temperature mode, the temperature result and temperature limit registers will be 13-bit instead of 12-bit. This extra bit increases the range of the measurement. As shown in Table 7-1, with a 12-bit temperature, the maximum value is 7FFh or 127.9 °C. With a 13-bit temperature value, however, the maximum value is FFFh or 255.9 °C.

When the extended temperature mode is enabled, the EM bit for the temperature high limit register and temperature low limit registers is usable by the application. TI recommends that the user update the T_{HIGH} and T_{LOW} register limits because the added bit will effectively left shift and double the register value. This will double the corresponding temperature limit. However, if the application exits the ETM mode, by changing the bit from 1 to 0, this bit is not cleared. As a result, the limit will be right-shifted by 1 bit and halved unless the register values are updated by the application.

The ETM bit value is considered at the end of every conversion cycle, but the limit registers can be updated immediately after setting the bit to 1.

7.4.5 Temperature Alert Function

The TMP144 contains a temperature alert function that monitors the device temperature and compares the result to the values stored in the temperature limit registers to determine if the device temperature is within these set limits. As shown in Figure 7-2, if the result of the temperature conversion is greater than the value in the temperature high limit register, the flag-high bit (FH) in the configuration register is set to '1'. If the result of the temperature conversion register is less than the value in the temperature low limit register, the flag-low (FL) in

the configuration register is set to '1'. The clearing of the flag bits depends on the setting of the latch bit (LC) in the configuration register.
Figure 7-2. Temperature Flag Functional Diagram

The LC bit in the configuration register when set to '1' is used to latch the value of the flag bits (FH and FL) until the host issues a read command to the configuration register. The flag bits are set to '0' when a read command is received by the device.

The LC bit when configured as '0', configures the device to operate in transparent mode, where the flag bits (FH and FL) are cleared only when the result of the temperature conversion is within the temperature limits.

7.4.6 Interrupt Functionality

The TMP144 interrupts the host by disconnecting the bus and issuing an interrupt request by holding the bus low if all of following conditions are met as shown in Figure 7-3.

- INT_EN in the configuration register is set to 1;
- The temperature result of the last conversion is greater than the value in the temperature high limit register or less than the value in the temperature low limit register (also indicated by a 1 in either FH or FL, respectively);
- The bus is logic high and idle for more than 28 ms.
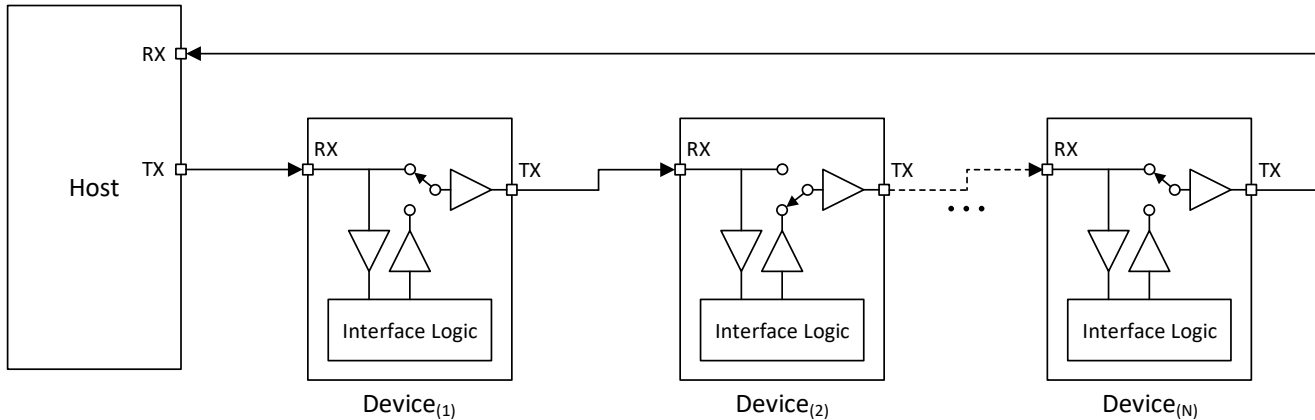

Figure 7-3. TMP144 Daisy-Chain: Bus Status During an Interrupt Request (Logic Low) From Second Device

The interrupt on the bus is latched regardless of the status of LC. Writing a 1 to INT_EN automatically sets the LC bit. The TMP144 holds the bus low until one of the following events happen:

- Global Interrupt Clear command is received.
- Global Software Reset command is received.
- A power-on reset event occurs.

Each of these events clears the INT_EN. The TMP144 does not issue future interrupts until the host writes sets the INT_EN in the configuration register to re-enable future interrupts.

In a system with enabled interrupts, it is possible for a TMP144 on the bus to issue an interrupt at the same time that the host starts a communication sequence. To avoid this scenario, TI recommends that the host should check the status on the receiving side of the bus after transmitting the calibration byte. If it is 1, then the host can continue with the communication. If it is 0, one of the TMP144 devices on the bus is issuing an alert and the host must transmit a Global Interrupt Clear command.

Product Folder Links: *TMP144*

7.5 SMAART Wire™ / UART Interface

The TMP144 uses a TI proprietary, one-wire UART-compatible communication protocol called SMAART Wire™. The TMP144 has two dedicated pins for communication:TX and RX. Usually, these two pins are connected internally and the signal on the RX propagates to the TX, unless the device must send data on the bus or during address assignment and alert procedures.

The interface has built-in timeouts (typically 28 ms) that return the interface to a known state if communication is disrupted.

7.5.1 Communication Protocol

Each communication of the SMAART Wire™ / UART protocol consists of 8-bit word, transferred least significant bit (LSB) first. Each 8-bit word begins with a *Start* bit that is logic low, and ends with a *Stop* bit that is logic high. By using a Start bit and Stop bit for each 8-bit word, the TMP144 can calibrate each word and keep synchronous communication throughout the process.

The steps for the SMAART Wire™ / UART communication protocol are:

1. The host sends a Start bit to start the communication process.
2. The host sends the calibration byte (55h) to allow the TMP144 to sync to the baud rate of the host.
3. The host sends a Stop bit after the calibration byte.
4. The host sends a second Start bit, followed by the command register byte and a Stop bit.
5. The host sends a third Start bit, followed by the data byte only for writes.
6. The host will send the data byte(s) if the instruction is a write command.
7. The host sends a Stop bit to finish the process.

Note
The device will break the chain and send the data byte(s) if the instruction sent in the command register is a read command.

The sequence is shown in Figure 7-4.

S = Start condition of SMAART Wire™ protocol
P = Stop condition of SMAART Wire™ protocol
Figure 7-4. Generic Communication Write Bitstream

S = Start condition of SMAART Wire™ protocol
P = Stop condition of SMAART Wire™ protocol
Figure 7-5. Generic Communication Read Bitstream

The command byte is decoded by the TMP144 to determine the format of the subsequent communication operation. Table 7-2 lists the command register byte values.

Table 7-2. Command Byte Value

COMMAND OPERATION	COMMAND BYTE ENCODING							HEX VALUE

7.5.2 Global Software Reset

The host can initiate a global software reset command (C[7:0] = 10110100) to all TMP144 devices in the daisy-chain as shown in Figure 7-6. Upon receiving this command, the TMP144 resets all of its internal registers except for the device ID and reconnects the bus. If the bus is broken before the initiation of this command, all TMP144 devices before the broken bus point receive the command. If the host intends to initiate a global software reset across all TMP144 devices in the chain, this command must be transmitted multiple times until it echoes back to the host.

Figure 7-6. Global Software Reset Command Flow

7.5.3 Global Initialization and Address Assignment Sequence

At device power-up, every TMP144 in the daisy-chain is connected in transparent mode, as shown in Figure 7-7.

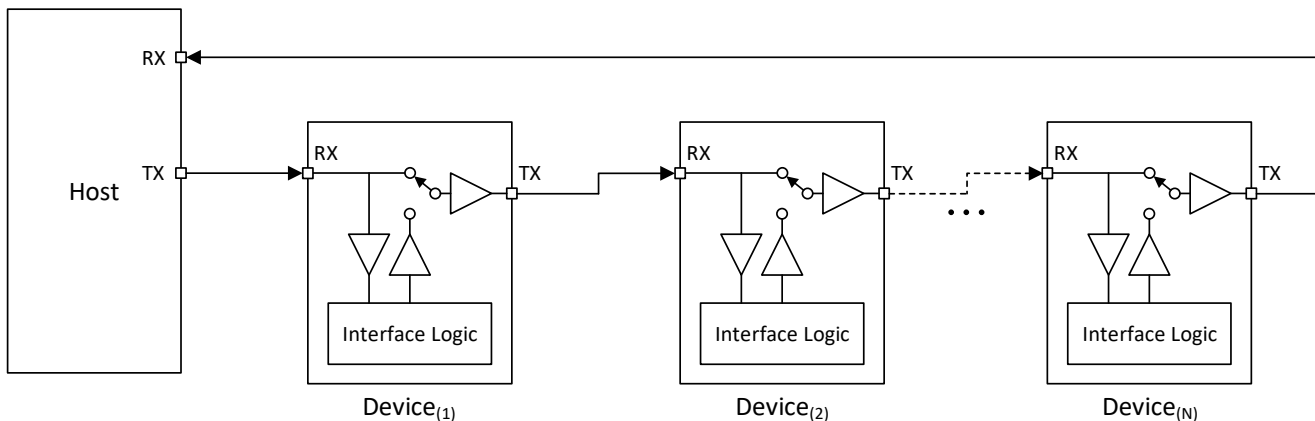

Figure 7-7. TMP144 Daisy-Chain: Bus Status at Start of Global Initialization

As shown in Figure 7-8, the host must send the initialization command (C[7:0] = 10001100) for the bus to program its internal address, depending on the number of devices on the bus.
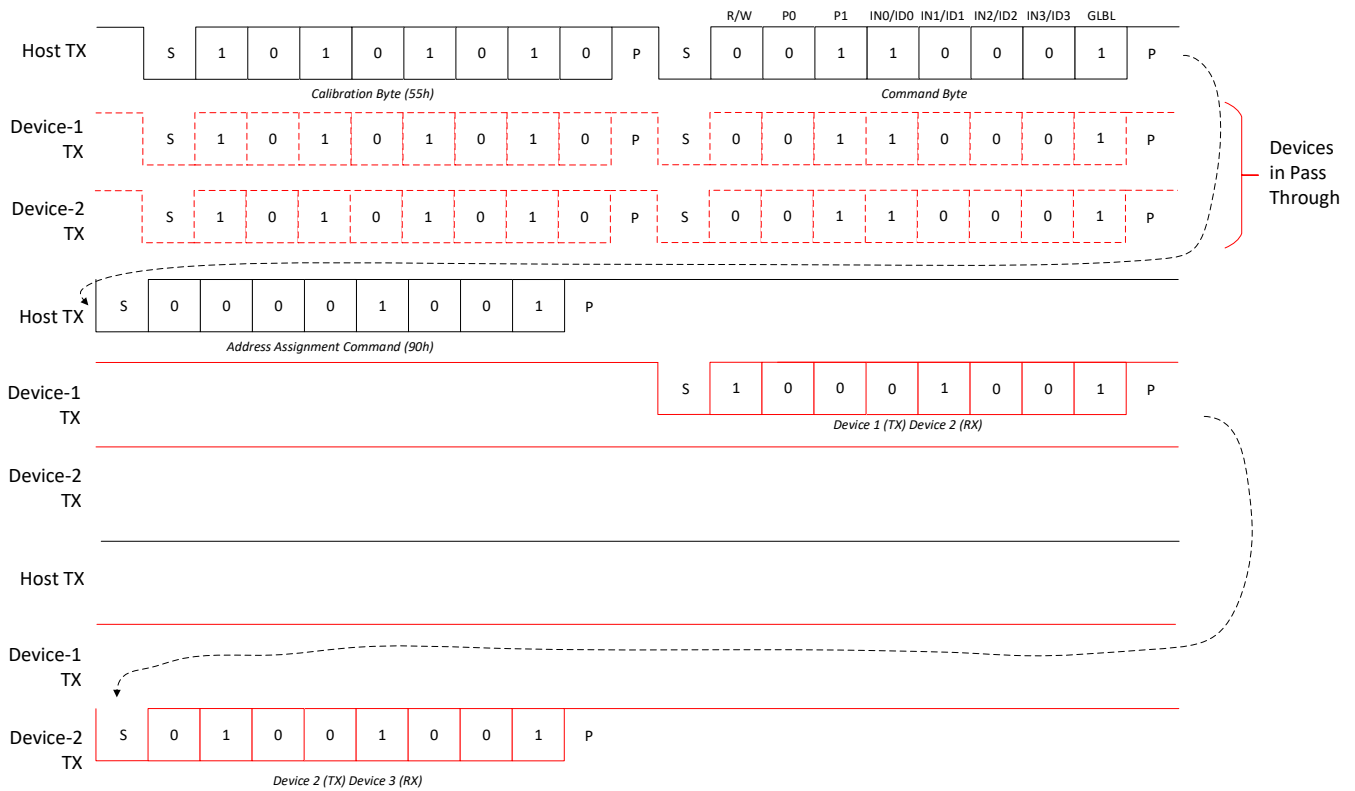

Figure 7-8. Global Initialization and Address Assignment Command Flow

Each TMP144 in the chain interprets the initialization command byte and disconnects the chain, as shown in Figure 7-9.
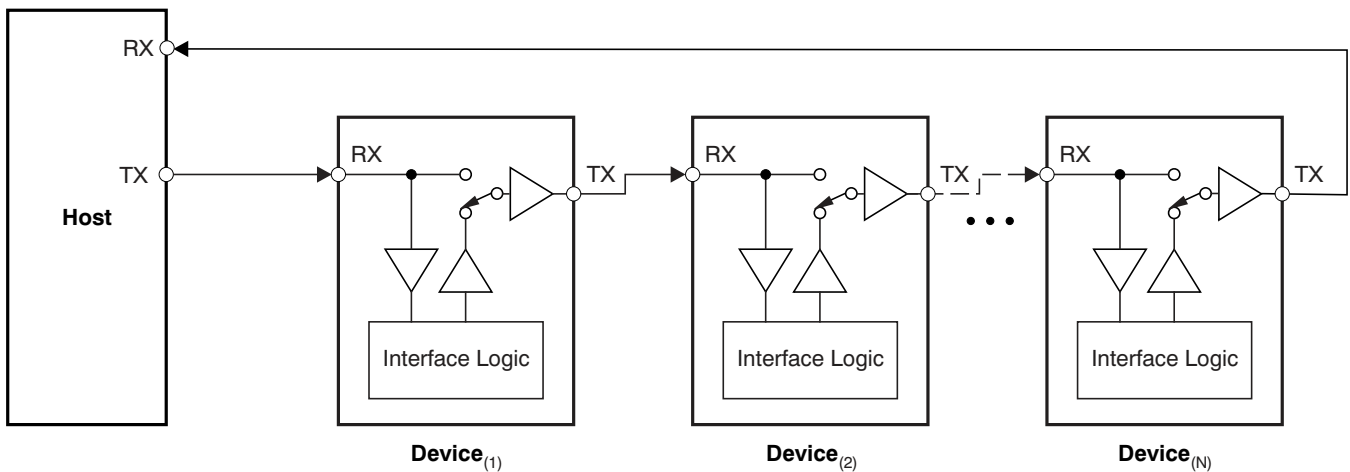

Figure 7-9. TMP144 Daisy-Chain: Bus Status at Start of Address Assignment

The host must then send the address assignment command, consisting of C[7:4] = 1001 and C[3:0] = 0000, where C[3:0] represents the address of the first device in the chain. This word is stored internally as its device ID. The first device increments the unit in the device address and then reconnects the bus, as shown in Figure 7-10. This address is then sent to the next device in the chain.

Product Folder Links: *TMP144*

Figure 7-10. TMP144 Daisy-Chain: Bus Status After First Device Address Assignment

After all devices on the chain have received the respective addresses, the host receives the last programmed address on the chain + 1. The host can use this information to determine the total number of devices in the chain and the respective address of each device.

After the initialization sequence, every device can be addressed individually or through global commands. This global initialization sequence is a requirement and must be performed before any other communication.

7.5.4 Global Clear Interrupt

The host can initiate a global clear interrupt command (C[7:0] = 10101001) to all TMP144 devices in the daisy-chain as shown in Figure 7-11. Upon receiving this command, the TMP144 disables future interrupts (bit-11 in the Configuration Register is set to 0). If a TMP144 previously broke the bus connection and sent an interrupt (logic low on the bus), the device now stops holding the bus low. The device sends the baud rate calibration command and clear interrupt command to the next TMP144 in the chain, then reconnects the bus. In the case of multiple devices having active interrupts, the clear interrupt command propagates through the daisy-chain, disables all interrupts, and reconnects the bus across all devices.
Figure 7-11. Global Clear Interrupt Command Flow

7.5.5 Global Read and Write

The host can initiate a global read or write command to all TMP144s in the daisy-chain by sending the read/write command, consisting of C[7:3] = 11110 and C[2:1] to indicate the data register pointer P[1:0], as shown in Table 7-3. A global write command is indicated by C[0] = 0. The host must transfer at least one more byte of data for the register, and every TMP144 in the daisy-chain updates the appropriate register as shown in Figure 7-12.

Figure 7-12. Global Write Command Flow

Product Folder Links: *TMP144*

A global read command is indicated by C[0] = 1. As shown in Figure 7-13, the TMP144 with the device ID of 0000 then breaks the bus connection, transmits the data from the register indicated by bits C[2:1] (corresponding to data register pointer P[1:0]), and then reconnects the bus. The TMP144 with the device ID of 0001 then repeats the same sequence, followed by the rest of the TMP144 devices in the daisy-chain.

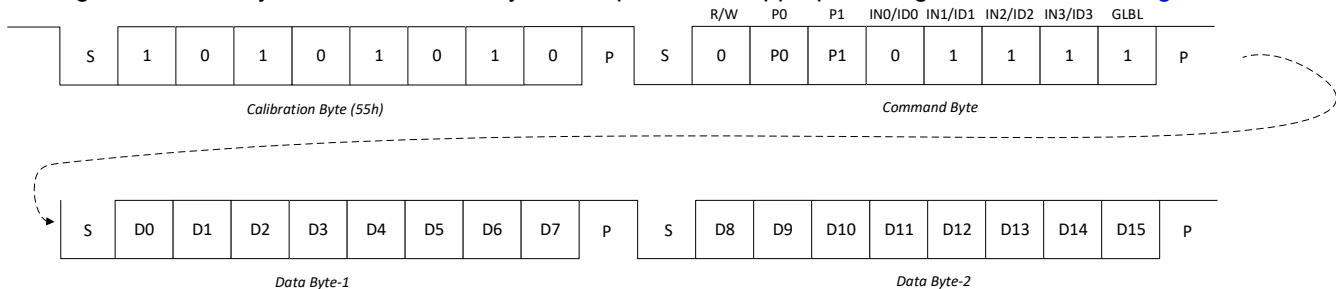

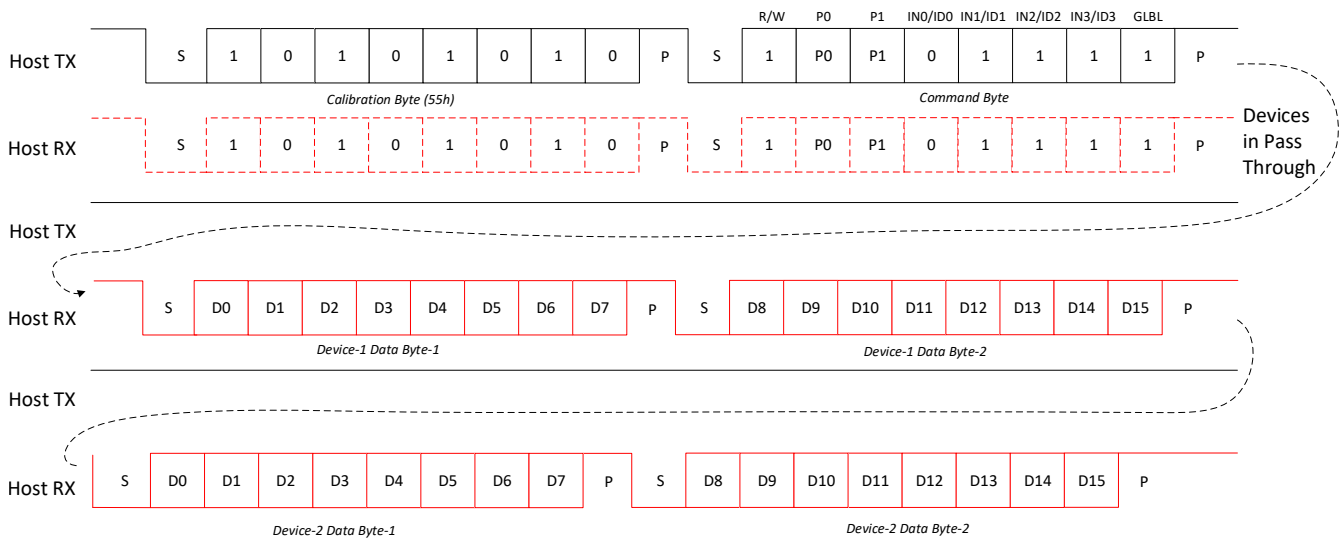

Figure 7-13. Global Read Command Flow

Table 7-3. Pointer Addresses

P1	P0	REGISTER
0	0	Temperature register (read-only)
0	1	Configuration register (read/write)
1	0	T_{LOW} register (read/write)
1	1	T_{HIGH} register (read/write)

7.5.6 Individual Read and Write

The host can initiate an individual read and write command to a particular TMP144 device in the daisy-chain by sending the read/write command. The read/write command consists of these parameters:

- C[7] = 0 (Individual device access)
- C[6:3] = the device ID (ID[3:0])
- C[2:1] = the data register pointer (P[1:0]); see Table 7-3
- C[0] = indicates read/write control

As shown in Figure 7-14, an individual device write command is indicated by C[0] = 0. The host must transfer at least one more byte of data for the register indicated by bits C[2:1]. The TMP144 in the daisy-chain that corresponds to the device ID noted by bits C[6:3] then updates the appropriate register.
Figure 7-14. Individual Write Command Flow

As shown in Figure 7-15, an individual device read command is indicated by C[0] = 1. As shown in Figure 7-16, the TMP144 in the daisy-chain that corresponds to the device ID pointed by bits C[6:3] then breaks the bus, transmits the data from the register pointed by bits C[2:1], and reconnects the bus.

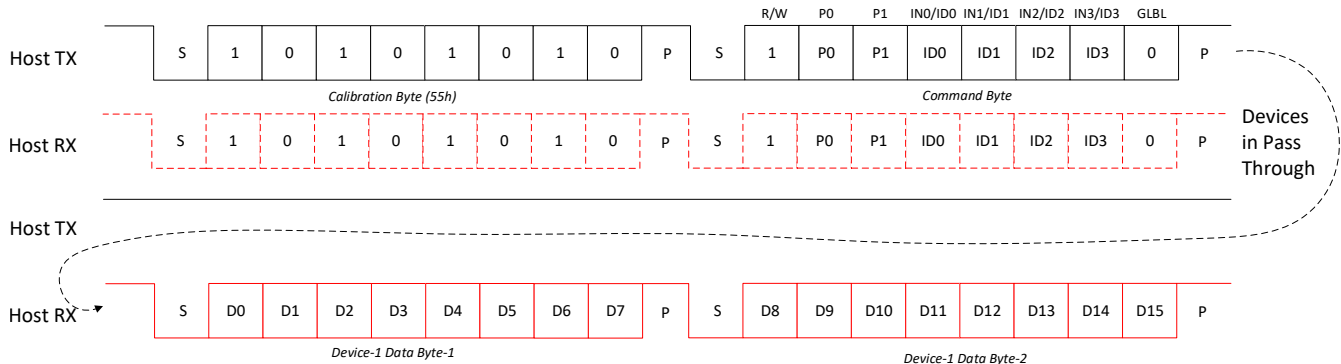

Figure 7-15. Individual Read Command Flow
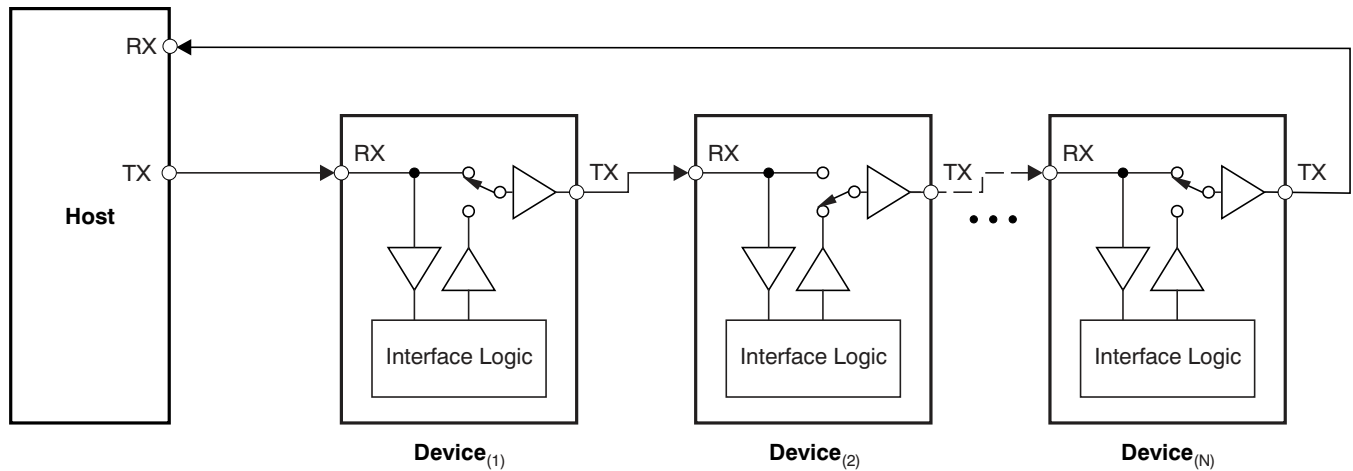

Figure 7-16. TMP144 Daisy-Chain: Bus Status During Individual Read Operation of Second Device

7.6 Register Maps

Figure 7-17 shows the internal register structure of the TMP144. Communications between the registers are transferred through the interface in LSB-first order. The 8-bit command register as shown in , is used to determine the address pointer for the register that the host device wants to access.
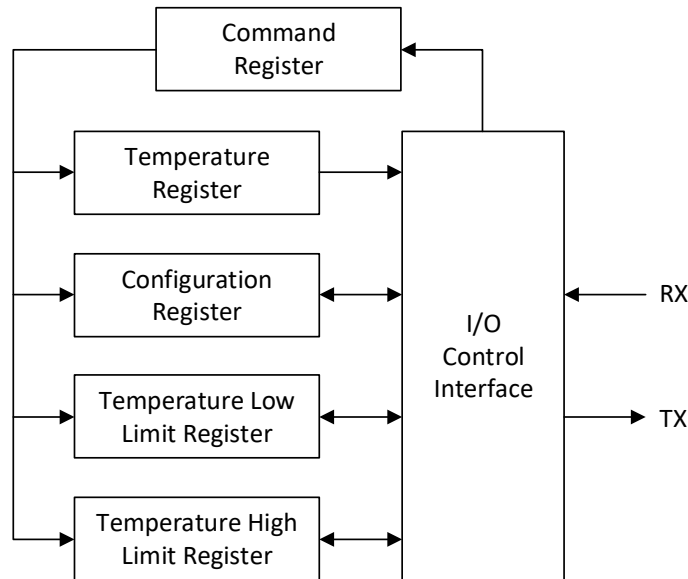

Figure 7-17. Internal Register Structure

Table 7-4. Register Map

ADDRESS POINTER P[1:0]	TYPE	RESET	ACRONYM	REGISTER NAME	SECTION
00	R	0000h	Temp_Result	Temperature result register	Go
01	R/W	0200h	Configuration	Configuration Register	Go
10	R/W	3C00h	Tlow_limit	Temperature low limit register	Go
11	R/W	F600h	Thigh_limit	Temperature high limit register	Go

Table 7-5. Register Section/Block Access Type Codes

Access Type	Code	Description
Read Type

RC	R	Read
	C	to Clear
R-0	R	Read
	-0	Returns 0s
Write Type		
W	W	Write
W0CP	W	W
	0C	0 to clear
	P	Requires privileged access
Reset or Default Value		
-n		Value after reset or the default value

7.6.1 Temperature Result Register (P[1:0] = 00) [reset = 0000h]

The temperature result register stores the results of the conversion in 12-bit or 13-bit format, depending on the state of the ETM bit in the configuration register. Negative numbers are represented in two's complement format. Following power-up or reset the temperature result register reads 0 °C, until the first conversion is complete.

When the ETM bit is configured as '0', the temperature result register of the device is configured as 12-bit value with the least significant bit always reading '0'. One LSB for the temperature result equals 0.0625 °C.

Table 7-6. Temperature Result Register (ETM = 0)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T[11:0]												EM	Reserved		
R-000h												R-0	R-0h		

Table 7-7. Temperature Result Register (ETM = 0) Field Description

Bit	Field	Type	Reset	Description
15:4	T[11:0]	R	000h	12-bit temperature result after last conversion
3	EM	R	0	Extended mode bit
2:0	Reserved	R	0h	Reserved

When the ETM bit is configured as '1', the temperature result register of the device is configured as 13-bit value. One LSB for the temperature result equals 0.0625 °C.

Table 7-8. Temperature Result Register (ETM = 1)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
T[12:0]													Reserved		
R-0000h													R-0h		

Table 7-9. Temperature Result Register (ETM = 1) Field Description

Bit	Field	Type	Reset	Description

2:0	Reserved	R	0h	Reserved

7.6.2 Configuration Register (P[1:0] = 01) [reset = 0200h]

The configuration register is used to store bits that control the operational modes of the temperature sensors and read the status of alert flags. Read/write operations are performed LSB first.

Return to Register Map.

Table 7-10. Configuration Register

7	ETM	R/W	0	Extended temperature mode select 0 = Mode is disabled 1 = Mode is enabled
6:0	Reserved	R	0	Reserved

7.6.3 Temperature Low Limit Register (P[1:0] = 10) [reset = F600h]

The temperature low limit register is used to store the low temperature threshold for the device low limit flag. The default power up reset value is -10 °C. The power on default value is valid only when ETM = 0. At the end of each temperature conversion, the device compares the temperature result with the temperature low limit register. If the temperature result is less than the threshold set in this register, the FL bit in the configuration register is set.

When the ETM bit in the configuration register is updated, it is strongly recommended that the user update the low limit register.

Note

When the ETM bit is set to 0, any writes to the EM bit will be ignored.

Table 7-12. Temperature Low Limit Register (ETM = 0)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
					L[11:0]							EM		Reserved	
					R/W-F60h							R/W-0		R-0h	

Table 7-13. Temperature Low Limit Register (ETM = 0) Field Description

Bit	Field	Type	Reset	Description
15:4	L[11:0]	R/W	F60h	12-bit temperature low limit threshold
3	EM	R/W	0	Don't care when ETM = 0
2:0	Reserved	R	0h	Reserved

Table 7-14. Temperature Low Limit Register (ETM = 1)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
						L[12:0]								Reserved	
						R/W-F600h								R-0h	

Table 7-15. Temperature Low Limit Register (ETM = 1) Field Description

Bit	Field	Type	Reset	Description
15:3	L[12:0]	R/W	F600h	13-bit temperature low limit threshold
2:0	Reserved	R	0h	Reserved

7.6.4 Temperature High Limit Register (P[1:0] = 11) [reset = 3C00h]

The temperature high limit register is used to store the high temperature threshold for the device high limit flag. The default power up reset value is +60 °C. The power on default value is valid only when ETM = 0. At the end of each temperature conversion, the device compares the temperature result with the temperature high limit register. If the temperature result is greater than the threshold set in this register, the FH bit in the configuration register is set.

When the ETM bit in the configuration register is updated, it is strongly recommended that the user update the high limit register.

Note

When the ETM bit is set to 0, any writes to the EM bit will be ignored.

Table 7-16. Temperature High Limit Register (ETM = 0)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
H[11:0]												EM	Reserved		
R/W-3C0h												R/W-0	R-0h		

Table 7-17. Temperature High Limit Register (ETM = 0) Field Description

8 Application and Implementation

> **Note**
>
> Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes, as well as validating and testing their design implementation to confirm system functionality.

8.1 Application Information

The TMP144 devices are typically used to for thermal management of multiple hotspots. The MDA commands make it easy to manage multiple devices at the same time, which reduces communication time and power. The WCSP package enables the device to be placed in space-constrained designs and allows the device to have a fast thermal response.

8.2 Typical Application

Figure 8-1 shows typical connections for TMP144 devices in a daisy-chain configuration.
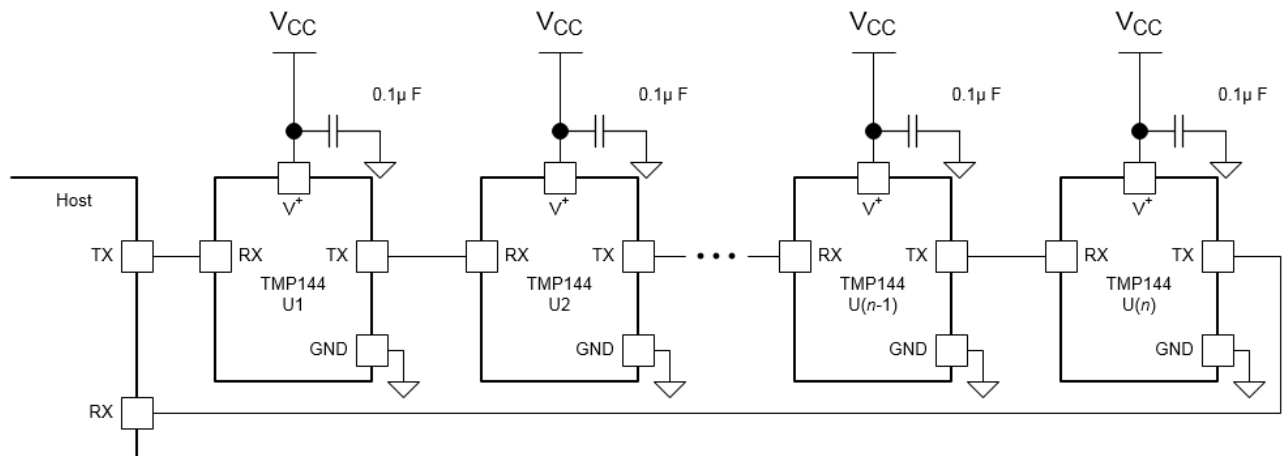

Figure 8-1. Typical Application With Multiple Devices

8.2.1 Design Requirements

Multiple devices are connected in this typical application. The key design requirements are discussed in the following sections.

8.2.2 Detailed Design Procedure

8.2.2.1 Trace Length

The maximum trace or cable length between two TMP144 devices can vary because of the effective resistance and capacitance of the type of cable used in a customer application. Design the trace or cable such that timing specifications in *Timing Diagrams* can be satisfied for each TMP144 device in the daisy-chain.
8.2.2.2 Voltage Drop Effect

Take into account the voltage drop that occurs along the supply and ground lines as a result of the currents of all the devices on the line. This voltage drop occurs as a result of multiple devices simultaneously consuming current through the combined resistance of the common wire, connectors, and solder contacts. Make sure that the supply on the last device does not fall below the minimum operating supply of 1.4 V.

8.2.2.3 Power Supply Noise Filtering

To reduce power supply noise, a 0.1-µF bypass capacitor is used for each TMP144 device. Depending on the environment, additional bypass capacitors (for example, 1 nF) may be required.

8.2.3 Application Curves

Figure 8-2. Typical Quiescent Current vs. Temperature

Figure 8-3. Temperature Error vs. Temperature

9 Power Supply Recommendations

The TMP144 operates on a power-supply range from 1.4 V to 3.6 V. The device is trimmed for operation at a 3.3-V supply, but the TMP144 can measure temperature accurately in the full supply range.

The TMP144 is a very low-power device and generates very low noise on the supply bus. Applying a bypass capacitor to the V+ pin of the TMP144 can further reduce any noise the TMP144 might propagate to other components. Use a C_F capacitor with a value greater than 0.1 µF as shown in Figure 9-1. Place the bypass capacitor as close to the supply and ground pins of the device as possible for best results.
Figure 9-1. Power Supply Noise Reduction With a Bypass Capacitor

10 Layout

10.1 Layout Guidelines

Mount the TMP144 to a PCB as shown in Figure 10-1. Obtaining acceptable performance with alternate layout schemes is possible, however this layout produces good results and is intended as a guideline:

- Bypass the V+ pin to ground with a low-ESR ceramic bypass-capacitor. The typical recommended bypass capacitance is a 0.1-µF ceramic capacitor with a X5R or X7R dielectric. The optimum placement is closest to the V+ and GND pins of the device. Take care to minimize the loop area formed by the bypass-capacitor connection, the V+ pin, and the GND pin of the IC. Alternatively, the bypass capacitor can also be grounded through a via connected to the GND plane.
- Use larger copper area pads to reduce self-heating and lower thermal resistance to the environment.
- If possible, use PCB boards with thick copper layers.
- If possible, do not use stain to protect the IC because stain can increase thermal resistance.
10.2 Layout Example

Figure 10-1. Layout Example

11 Device and Documentation Support

11.1 Device Support

11.1.1 Device Nomenclature

daisy-chain A method of propagating signals along a bus in which the devices are connected in series and the signal passed from one device to the next. The daisy-chain scheme permits assignment of device priorities based on the electrical position of the device on the bus.

11.2 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on ti.com. In the upper right corner, click on *Alert me* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

11.3 Support Resources

TI E2E™ support forums are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's Terms of Use.

11.4 Trademarks

SMAART Wire™ and TI E2E™ are trademarks of Texas Instruments.
All trademarks are the property of their respective owners.

11.5 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

11.6 Glossary

TI Glossary   This glossary lists and explains terms, acronyms, and definitions.

# 12 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

TMP144YMTT	ACTIVE	PICOSTAR	YMT	4	250	RoHS & Green	CUNIPD	Level-1-260C-UNLIM	-40 to 125		Samples

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
