

The Infinite Bandwidth Company™

# MIC833

## Comparator and Reference with Adj. Hysteresis

### Final Information

### General Description

The MIC833 is a micropower precision dual voltage comparator with an on-chip reference and latch.

High- and low-voltage thresholds are adjusted independently, allowing for wide hysteresis. Three external resistors determine the threshold voltages. Voltage detection thresholds are accurate to 1.5%.

Supply current is extremely low (1µA, typical), making it ideal for portable applications.

The MIC833 is supplied in Micrel's IttyBitty™ 5-lead SOT-23-5 package.

See the MIC2778 for applications requiring an output delay.

### Features

- Optimized for PDAs, cellular telephones, pagers, and other battery-powered devices
- Inputs and output can pulled up to 6V regardless of supply voltage
- Independently adjustable high- and low-voltage thresholds
- High ±1.5% voltage threshold accuracy
- Extremely low 1µA typical supply current
- Immune to brief input transients
- 5-lead SOT-23 package

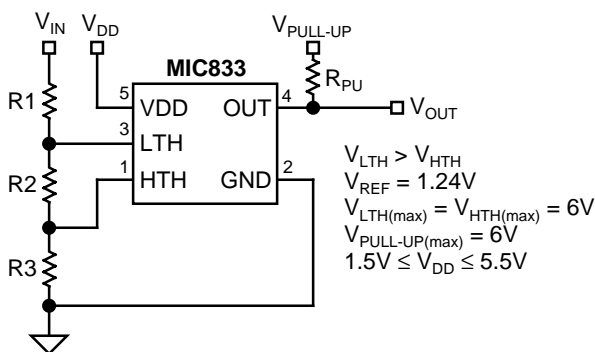

### Applications

- PDAs
- Pagers
- Cordless phones
- Consumer electronics
- Embedded controllers
- Personal electronics

### Ordering Information

Part Number	Marking	Accuracy	Temperature Range	Package
MIC833BM5	B11	1.5%	-40°C to +85°C	SOT-23-5

### Typical Application

IttyBitty™ is a trademark of Micrel, Inc.

## Pin Configuration

**SOT-23-5 (M5)**

## Pin Description

Pin Number	Pin Name	Pin Function
1	HTH	High-Voltage Threshold (Input): Analog input to a comparator. This is the voltage input assigned to detect a high-voltage condition when the level on this pin exceeds $V_{REF}$ , OUT is asserted and the condition is latched until $V_{LTH} < V_{REF}$ .
2	GND	Ground
3	LTH	Low-Voltage Threshold (Input): Analog input to a comparator. This is the voltage input assigned to detect a low voltage condition. When the level on this pin falls below $V_{REF}$ , OUT is de-asserted and the condition is latched until $V_{HTH} > V_{REF}$ .
4	OUT	Output: Active-high, open-drain output. This output is de-asserted and latched when $V_{LTH} < V_{REF}$ , indicating a low voltage condition. This state remains latched until $V_{HTH} > V_{REF}$ .
5	VDD	Power Supply (Input): Independent supply input for internal circuitry.

### Absolute Maximum Ratings (Note 1)

Supply Voltage ( $V_{DD}$ )	-0.3V to +7V
Input Voltages ( $V_{LTH}$ , $V_{HTH}$ )	+7V
Output Current ( $I_{OUT}$ )	20mA
Storage Temperature ( $T_S$ )	-65°C to +150°C
ESD Rating, <b>Note 3</b>	2kV

### Operating Ratings (Note 2)

Supply Voltage ( $V_{DD}$ )	+1.5V to +5.5V
Input Voltage ( $V_{LTH}$ , $V_{HTH}$ )	-0.3V to +6V
Ambient Temperature Range ( $T_A$ )	-40°C to +85°C
Junction Temperature ( $T_J$ )	Internally Limited
Package Thermal Resistance ( $\theta_{JA}$ )	260°C/W

### Electrical Characteristics

1.5V ≤  $V_{DD}$  ≤ 5.5V;  $T_A$  = +25°C, **bold** values indicate -40°C ≤  $T_A$  ≤ +85°C; unless noted

Symbol	Parameter	Condition	Min	Typ	Max	Units
$I_{DD}$	Supply Current	outputs not asserted		1	<b>2</b>	μA
$I_{LTH}$ , $I_{HTH}$	Input Leakage Current			0.005	<b>10</b>	nA
$V_{REF}$	Reference Voltage		<b>1.221</b>	1.240	<b>1.259</b>	V
$t_D$	Propagation Delay	$V_{LTH} = 1.352V$ to $1.128V$		5		μs
		$V_{HTH} = 1.128V$ to $1.352V$		5		μs
$V_{OUT}$	Output Voltage-Low, <b>Note 4</b>	OUT de-asserted, $I_{SINK} = 1.6mA$ , $V_{DD} \geq 1.6V$			<b>0.3</b>	V
		OUT de-asserted, $I_{SINK} = 100\mu A$ , $V_{DD} \geq 1.2V$			<b>0.4</b>	V

- Note 1.** Exceeding the absolute maximum rating may damage the device.
- Note 2.** The device is not guaranteed to function outside its operating rating.
- Note 3.** Devices are ESD sensitive. Handling precautions recommended. Human body model, 1.5k in series with 100pF.
- Note 4.**  $V_{DD}$  operating range is 1.5V to 5.5V. output is guaranteed to be held low down to  $V_{DD} = 1.2V$ .

### Functional Diagram

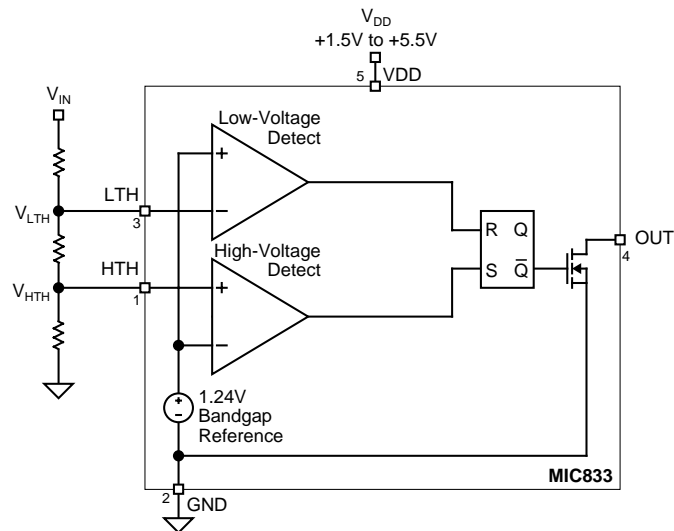

- Note A.** Brief transients are ignored by the MIC833. See “Applications Information.”
- Note B.**  $V_{LTH} > V_{LO} > V_{REF}$ .

### Timing Diagram

## Block Diagram

## Functional Description

The MIC833 monitors a voltage and detects when it is below or above two independently programmed levels.

### Voltage Low Output

The output (OUT) is an active-high, open-drain output which sinks current when the MIC833 detects a low input voltage at its LTH input. This condition is latched until the HTH input is presented with a voltage higher than the internal  $V_{REF}$  (+1.24V).

## Trip Points

Input voltage is monitored by the comparators via a voltage divider network. The divided voltage is compared to an internal reference voltage. When the voltage at the LTH input pin drops below the internal reference voltage, the output pulls low. Because of the voltage divider, the voltage at HTH input is assured to be below the reference voltage.

## Applications Information

### Output

Since the MIC833 output is an open-drain MOSFET, most applications will require a pull-up resistor. The value of the resistor should not be too large or leakage effects may dominate. 470kΩ is the maximum recommended value. Note that the output may be pulled up as high as 6V regardless of IC supply voltage. See “Electrical Characteristics.”

### Programming the Thresholds

The low-voltage threshold is calculated using:

$$V_{IN(lo)} = V_{REF} \left( \frac{R1 + R2 + R3}{R2 + R3} \right)$$

The high-voltage threshold is calculated using:

$$V_{IN(hi)} = V_{REF} \left( \frac{R1 + R2 + R3}{R3} \right)$$

where, for both equations:

$$V_{REF} = 1.240V$$

In order to provide the additional criteria needed to solve for the resistor values, the resistors can be selected such that they have a given total value, that is,  $R1 + R2 + R3 = R_{TOTAL}$ . A value such as 1MΩ for  $R_{TOTAL}$  is a reasonable value because it draws minimum current but has no significant effect on accuracy.

When working with large resistors, a small amount of leakage current can cause voltage offsets that degrade system accuracy. The maximum recommended total resistance from  $V_{IN}$  to ground is 3MΩ.

Figure 1. Example Circuit

Once the desired trip points are determined, set the  $V_{IN(hi)}$  threshold first.

For example, use a total of  $1M\Omega = R1 + R2 + R3$ . For a typical single-cell lithium ion battery, 3.6V is a good “high threshold” because at 3.6V the battery is moderately charged. Solving for R3:

$$V_{IN(hi)} = 3.6V = 1.24 \left( \frac{1M\Omega}{R3} \right)$$

$$R3 = 344k\Omega$$

Once R3 is determined, the equation for  $V_{IN(lo)}$  can be used to determine R2. A single lithium-ion cell, for example, should not be discharged below 2.5V. Many applications limit the

drain to 3.1V. Using 3.1V for the  $V_{IN(lo)}$  threshold allows calculation of the two remaining resistor values.

$$V_{IN(lo)} = 3.1V = 1.24 \left( \frac{1M\Omega}{R2 + 344k} \right)$$

$$R2 = 56k\Omega$$

$$1M\Omega - (R2 + R3) = R1$$

$$R1 = 600k\Omega$$

The accuracy of the resistors can be chosen based upon the accuracy required by the system.

The inputs may be subjected to voltages as high as 6V steady state without adverse effects of any kind, regardless of the IC supply voltage. This applies even if the supply voltage is zero. This permits the situation in which the IC supply is turned off, but voltage is still present on the inputs. See “Electrical Characteristics.”

### Input Transients

The MIC833 is inherently immune to very short negative-going “glitches.” Very brief transients may exceed the  $V_{IN(lo)}$  threshold without tripping the output.

As shown in Figure 2, the narrower the transient, the deeper the threshold overdrive that will be ignored by the MIC833. The graph represents the typical allowable transient duration for a given amount of threshold overdrive that will not toggle the output.

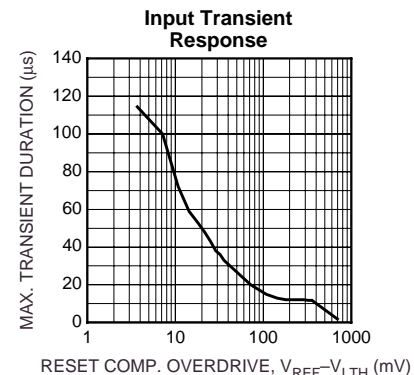

Figure 2. Input Transient Response

### Initialization Behavior

When the MIC833 is powered up, the comparators and latch become active before the reference voltage reaches its final value. In most applications, this presents no problems. However, the user should be aware of this: when applying power to the part, if the input voltage is *between* the two thresholds, the output of the part will be *high* because input HTH will have been higher than the 1.24V reference during initialization.

It is not very likely the part would be powered up in this state; it is more likely the same power supply will power the part and develop its inputs. However, if the above-described condition should occur, the next HTH threshold crossing would *not* be processed; that is, the latch would have been already set. The next valid input condition would have to be a crossing of the LTH threshold, which resets the latch, after which “normal” operation is restored.
