

ISL81805EVAL2Z

The ISL81805EVAL2Z dual-output evaluation board (shown in [Figure 4](#)) features the [ISL81805](#), an 80V high voltage dual synchronous boost controller that offers external soft-start, independent enable functions, and integrates UV/OV/OC/OT protection. A programmable switching frequency ranging from 100kHz to 1MHz helps to optimize inductor size while the strong gate driver delivers up to 3A for Channel 1 and 5A for Channel 2.

Specifications

The ISL81805EVAL2Z dual output evaluation board is designed for high output voltage applications. The current rating of the ISL81805EVAL2Z is limited by the FETs and inductor selected. The ISL81805EVAL2Z electrical ratings listed in [Table 1](#).

Table 1. ISL81805EVAL2Z Electrical Ratings

Parameter	Rating
Input Voltage 1	9V to 36V
Input Voltage 2	9V to 20V
Switching Freq	200kHz
Output Voltage 1	48V
Output Current 1	3A
Output Voltage 2	24V
Output Current 2	5A
OCP Set Point 1 (input average)	Minimum 13.8A at ambient room temperature
OCP Set Point 2 (input average)	Minimum 12.6A at ambient room temperature

Features

- Wide input range: 9V to 36V for 48V output, 9V to 20V for 24V output
- High light-load efficiency in pulse skipping DEM operation
- Programmable soft-start
- Optional DEM/PWM operation
- Optional CC/HICCUP OCP protection
- Supports pre-bias output with soft-start
- PGOOD indicator
- OVP, OTP, and UVP protection
- External bias to improve efficiency
- Optional input/output average OCP

1. Functional Description

The ISL81805EVAL2Z is the same test board used by Renesas application engineers and IC designers to evaluate the performance of the ISL81805 TQFN IC. The board provides an easy and complete evaluation of all the IC and board functions.

As shown in [Figure 3](#), the 9V to 36V V_{IN1} is supplied to J1 (+) and J2 (-). The regulated 48V output V_{O1} is on J4 (+) and J5 (-). Because of the high-power efficiency, Channel 1 can run at 3A continuously without airflow at ambient room temperature conditions. The 9V to 20V V_{IN2} is supplied to J20 (+) and J21 (-). The regulated 24V output V_{OUT2} is on J17 (+) and J16 (-). Because of the high-power efficiency, Channel 2 can run at 5A continuously without airflow at ambient room temperature conditions.

Test points TP1 through TP26 provide easy access to the IC pin and external signal injection terminals.

As shown in [Table 2](#), connector J6 provides a selection of either Forced PWM mode (shorting Pin 1 and Pin 2) or DEM mode (shorting Pin 2 and Pin 3). Connector J7 provides a selection of either constant current limit (shorting Pin 1 and Pin 2) or HICCUP OCP (shorting Pin 2 and Pin 3). Connector J3 and J19 provide an option to disable each output respectively by shorting their Pin 1 and Pin 2.

1.1 Recommended Testing Equipment

The following materials are recommended for testing:

- 0V to 40V power supply with at least 25A source current capability
- Electronic loads capable of sinking current up to 7A
- Digital Multimeters (DMMs)
- 100MHz quad-trace oscilloscope

1.2 Operating Range

The input voltage range is from 9V to 36V for the 48V output, while the input voltage range is from 9V to 20V for the 24V output. If the output voltage is set to a lower value, the minimum V_{IN} can be reset to a lower value by changing the ratio of R_1 and R_5 . The minimum EN threshold that V_{IN} can be set to is 4.5V.

The rated load currents for each output are 3A and 5A with the input OCP point set at a minimum 13.8A for Channel 1 and 12.6A for Channel 2 at ambient room temperature conditions. The operating temperature range of this board is -40°C to +85°C.

Note: Airflow is needed for higher ambient temperature conditions.

1.3 Quick Test Guide

1. Jumper J6 provides the option to select PWM or DEM. Jumper J7 provides the option to select a constant current limit or HICCUP. See [Table 2](#) for the operating options. Ensure that the circuit is correctly connected to the supply and electronic loads before applying any power. See [Figure 3](#) for the proper setup.
2. Turn on the power supply.
3. Adjust the input voltage (V_{IN}) within the specified range and observe the output voltage. The output voltage variation should be within 3%.
4. Adjust the load current within the specified range and observe the output voltage. The output voltage variation should be within 3%.
5. Use an oscilloscope to observe output voltage ripple and phase node ringing. For accurate measurement, see [Figure 2](#) for the proper test setup.

Note: Renesas recommends adding a minimum 0.1A load current if configured as DEM.

Table 2. Operating Options

Jumper	Position	Function
3	EN1-GND	Disable 48V output
	EN1 Floating	Enable 48V output
19	EN2-GND	Disable 24V output
	EN2 Floating	Enable 24V output
6	Pin 1-2	PWM
	Pin 2-3	DEM
7	Pin 1-2	Constant current limit
	Pin 2-3	HICCUP

2.1 PCB Layout Guidelines

Careful attention to Printed Circuit Board (PCB) layout requirements is necessary for the successful implementation of an ISL81805 based DC/DC converter. The ISL81805 switches at a high frequency; therefore, the switching times are short. At these switching frequencies, even the shortest trace has significant impedance and the peak gate drive current rises significantly in an extremely short time. The transition speed of the current from one device to another causes voltage spikes across the interconnecting impedances and parasitic circuit elements. These voltage spikes can degrade efficiency, generate EMI, and increase device voltage stress and ringing. Careful component selection and proper PCB layout minimize the magnitude of these voltage spikes.

Three sets of components are critical when using the ISL81805 DC/DC converter:

- Controller
- Switching power components
- Small-signal components

The switching power components are the most critical to the layout because they switch a large amount of energy, which tends to generate a large amount of noise. The critical small-signal components are those connected to sensitive nodes or those supplying critical bias currents. A multilayer PCB is recommended.

Complete the following steps to optimize the PCB layout.

- Place the input capacitors, inductor, boost FETs, and output capacitor first. Isolate these power components on dedicated areas of the board with their ground terminals adjacent to one another. Place the input and output high frequency decoupling ceramic capacitors close to the MOSFETs.
- If signal components and the IC are placed in a separate area to the power train, use full ground planes in the internal layers with shared SGND and PGND to simplify the layout design. Otherwise, use separate ground planes for the power ground and the small-signal ground. Connect the SGND and PGND close to the IC. DO NOT connect them anywhere else.
- Keep the loop formed by the output capacitor, the boost top FET, and the boost bottom FET as small as possible.
- Keep the current paths from the input capacitor to the power inductor, the boost FETs, and the output capacitor as short as possible with maximum allowable trace widths.
- Place the PWM controller IC close to the lower FETs. The low-side FETs gate drive connections should be short and wide. Place the IC over a quiet ground area. Avoid switching ground loop currents in this area.
- Place the VDD bypass capacitor close to the VDD pin of the IC and connect its ground end to the PGND pin. Connect the PGND pin to the ground plane using a via. DO NOT directly connect the PGND pin to the SGND EPAD.
- Place the gate drive components (BOOT diodes and BOOT capacitors) together near the controller IC.
- Use copper filled polygons or wide short traces to connect the junction of the upper FET, lower FET, and output inductor. Also, keep the PHASE nodes connection to the IC short. DO NOT oversize the copper islands for the PHASE nodes. Because the phase nodes are subjected to high dv/dt voltages, the stray capacitor formed between these islands and the surrounding circuitry tends to couple switching noise.
- Route all high-speed switching nodes away from the control circuitry.
- Create a separate small analog ground plane near the IC. Connect the SGND pin to this plane. Connect all small signal grounding paths including feedback resistors, current monitoring resistors and capacitors, soft-starting capacitors, loop compensation capacitors and resistors, and EN pull-down resistors to this SGND plane.
- Use a pair of traces with minimum loop for the input or output current sensing connection.
- Ensure the feedback connection to the output capacitor is short and direct.

Figure 9. Second Layer (Solid Ground)

Figure 10. Third Layer

Figure 11. Bottom Layer

Figure 12. Silkscreen Bottom

2.5 Design Procedure

2.5.1 Design Requirements

Parameter	Rating
Input Voltage	9V to 36V for 48V output 9V to 20V for 24V output
Switching Frequency	200kHz
Output Voltage 1	48V
Output Current 1	3A
Output Voltage 2	24V
Output Current 2	5A
OCP Set Point (input average)	13.8A for 48V output, 12.6A for 24V output
Output Mode	Dual output
PWM Mode	Forced PWM
OCP Mode	Constant current

2.5.2 Frequency Setting

The default switching frequency of the PWM controller is determined by the resistor R_T (R19). It adjusts the default switching frequency from 100kHz to 1MHz. The R_T value for $f_{SW} = 200\text{kHz}$ is calculated using [Equation 1](#).

$$(EQ. 1) \quad R_T = \left(\frac{34.7}{f_{SW}} - 4.78 \right) = \frac{34.7}{0.2} - 4.78 = 168.72\text{k}\Omega$$

where f_{SW} is the switching frequency in MHz. Select a standard value resistor $R_T = 169\text{k}\Omega$.

2.5.3 Output Voltage Setting

The output voltage can be set from 0.8V up to a level determined by the feedback voltage divider. A resistive divider from the output to ground sets the output voltage. Connect the center point of the divider to the FB1 pin. With $V_{OUT1} = 48V$, R_{FBO1} (R2) = 205k, the R_{FBO2} (R12) value is calculated using Equation 2.

$$(EQ. 2) \quad R_{FBO2(12V)} = \frac{0.8V \times R_{FBO1}}{V_{OUT1} - 0.8V} = \frac{0.8V \times 205k\Omega}{48V - 0.8V} = 3.47k\Omega$$

Select a standard value resistor $R_{FBO2} = 3.48k\Omega$.

With $V_{OUT2} = 24V$, R_{FBO1} (R53) = 113k, the R_{FBO2} (R39) value is calculated using Equation 3.

$$(EQ. 3) \quad R_{FBO2(5V)} = \frac{0.8V \times R_{FBO1}}{V_{OUT2} - 0.8V} = \frac{0.8V \times 113k\Omega}{24V - 0.8V} = 3.89k\Omega$$

Select a standard value resistor $R_{FBO2} = 3.9k\Omega$. R_{FBO1} is the top resistor of the feedback divider network and R_{FBO2} is the bottom resistor connected from FB1 to ground.

2.5.4 UVLO Setting

The ISL81805 has input UVLO protection. When the voltage on the EN/UVLO pin reaches 1.8V, the PWM modulator is enabled. Accurate UVLO feature can be implemented by feeding the V_{IN} into the EN/UVLO pin using a voltage divider, R_{UV1} (R1) and R_{UV2} (R5). The V_{IN} UVP rising threshold is calculated using Equation 4.

$$(EQ. 4) \quad V_{UVRISE} = \frac{V_{UVLO_THR}(R_{UV1} + R_{UV2}) - I_{LEAK}R_{UV1}R_{UV2}}{R_{UV2}} = \frac{1.8V(200k\Omega + 51k\Omega) - 1.4\mu A(200k\Omega)(51k\Omega)}{51k\Omega} = 8.58V$$

The V_{IN} UVP falling threshold is calculated using Equation 5.

$$(EQ. 5) \quad V_{UVFALL} = \frac{V_{UVLO_THR}(R_{UV1} + R_{UV2}) - I_{UVLO_HYST} R_{UV1}R_{UV2}}{R_{UV2}} \\ = \frac{1.8V(200k\Omega + 51k\Omega) - 3.4\mu A(200k\Omega)(51k\Omega)}{51k\Omega} = 8.18V$$

where V_{UVLO_THR} is the 1.8V UVLO rising threshold and I_{UVLO_HYST} is the 3.4 μ A UVLO hysteresis current.

2.5.5 Soft-Start Capacitor

The soft-start time for dual output is set by the value of the soft-start capacitor C_{SS1} (C22) connected from SS/TRK1 to GND and C_{SS2} (C47) connected from SS/TRK2 to GND separately. The soft-start time with $C_{SS1} = C_{SS2} = 47nF$ is calculated using Equation 6.

$$(EQ. 6) \quad t_{SS} = 0.8V \left(\frac{C_{SS}}{2\mu A} \right) = 0.8V \times \left(\frac{47nF}{2\mu A} \right) = 18.8ms$$

When the soft-start time set by external C_{SS} or tracking is less than 1.7ms, an internal soft-start circuit of 1.7ms takes over the soft-start.

2.5.6 MOSFET Considerations

The MOSFETs are selected based on $r_{DS(ON)}$, gate supply requirements, and thermal management considerations.

The power loss of the upper and lower MOSFETs for the 48V output are calculated using [Equation 7](#) and [Equation 8](#). The equations assume linear voltage current transitions and ignore the power loss caused by the reverse recovery of the body diode of the lower MOSFET.

$$\begin{aligned}
 P_{\text{LOWERMAX}} &= \left[\frac{(I_{\text{OUT}})^2 (V_{\text{OUT}})^2}{(V_{\text{INMIN}})^2} \right] \frac{(V_{\text{OUT}} - V_{\text{INMIN}})(r_{\text{DS(ON)}})}{V_{\text{OUT}}} + \frac{(I_{\text{OUT}})(V_{\text{OUT}})^2 (t_{\text{SW}})(f_{\text{SW}})}{2(V_{\text{INMIN}})} \\
 \text{(EQ. 7)} \quad &= \left[\frac{\left(\frac{3\text{A}}{2}\right)^2 (48\text{V})^2}{(12\text{V})^2} \right] \frac{(48\text{V} - 12\text{V})(6\text{m}\Omega)}{48\text{V}} + \frac{\left(\frac{3\text{A}}{2}\right)(48\text{V})^2 \left(\frac{6\text{nC}}{\left(\frac{8\text{V} - 4.9\text{V}}{1\Omega}\right)} + \frac{6\text{nC}}{\left(\frac{4.9\text{V}}{1\Omega}\right)} \right) (200\text{kHz})}{2(12\text{V})} = 0.162\text{W} + 0.09\text{W} = 0.252\text{W}
 \end{aligned}$$

$$\text{(EQ. 8)} \quad P_{\text{UPPERMAX}} = \frac{(I_{\text{OUT}})^2 (r_{\text{DS(ON)}})(V_{\text{OUT}})}{V_{\text{INMIN}}} = \frac{\left(\frac{3\text{A}}{2}\right)^2 (6\text{m}\Omega)(48\text{V})}{12\text{V}} = 0.054\text{W}$$

Ensure that all MOSFETs are within their maximum junction temperature with enough margin at high ambient temperature by calculating the temperature rise according to package thermal resistance specifications.

2.5.7 Inductor Selection

The inductor value determines the ripple current of the converter. To limit the inductor core loss, the inductor ripple current is usually 40-80% of the rated output current. Assume the ripple current ratio is 80% of the inductor average current at the maximum input voltage and the full output load condition. The inductor value for the 48V output is calculated using [Equation 9](#).

$$\text{(EQ. 9)} \quad L_{\text{INMIN}} = \frac{(V_{\text{OUT}} - V_{\text{INMIN}})(V_{\text{INMIN}})}{(f_{\text{SW}})(0.8 \times I_{\text{INMAX}})(V_{\text{OUT}})} = \frac{(48\text{V} - 12\text{V})(12\text{V})}{(200\text{kHz})\left(0.8 \times \frac{48\text{V} \times 3\text{A}}{12\text{V} \times 2}\right)(48\text{V})} = 9.375\mu\text{H}$$

The recommended inductor value is 10 μH . Then the ripple current and peak current are calculated using [Equation 10](#), [Equation 11](#), and [Equation 12](#).

$$\text{(EQ. 10)} \quad \Delta I_{\text{LMAX}} = \frac{(V_{\text{OUT}} - V_{\text{IN}})(V_{\text{IN}})}{(f_{\text{SW}})(L)(V_{\text{OUT}})} = \frac{(48\text{V} - 12\text{V})(12\text{V})}{(200\text{kHz})(10\mu\text{H})(48\text{V})} = 4.5\text{A}$$

$$\text{(EQ. 11)} \quad I_{\text{LRMSMAX}} = \sqrt{(I_{\text{INMAX}})^2 + \frac{(\Delta I_{\text{LMAX}})^2}{12}} = \sqrt{\left(\frac{48\text{V} \times 3\text{A}}{12\text{V} \times 2}\right)^2 + \frac{(4.5\text{A})^2}{12}} = 6.14\text{A}$$

$$\text{(EQ. 12)} \quad I_{\text{LPEAKMAX}} = I_{\text{INOC1}} + \frac{\Delta I_{\text{LMAX}}}{2} = 11\text{A} + \frac{4.5\text{A}}{2} = 13.25\text{A}$$

The saturation current of the inductor should be larger than 13.25A. The heat rating current of the inductor should be larger than 6.14A.

With inductor 74439370100 from Würth Electronics, the maximum DC power dissipation in the inductor is approximately calculated using [Equation 13](#).

$$\text{(EQ. 13)} \quad P_{\text{LMAX}} = (I_{\text{LRMS}})^2 (\text{DCR}) = (6.14\text{A})^2 \times (6.4\text{m}\Omega) = 0.241\text{W}$$

2.5.8 Output Capacitor Selection

The maximum capacitor value required to provide the full, rising step, transient load current during the response time of the inductor for the 48V output is shown in [Equation 14](#).

$$(EQ. 14) \quad C_{OUTMIN} = \frac{L(V_{OUT})(I_{TRAN})^2}{2(V_{INMIN})^2(\Delta V_{OUT})} = \frac{10\mu H \times (48V) \times \left(\frac{3A}{2} - 0A\right)^2}{2(12V)^2\left(48V \times \frac{1}{100}\right)} = 7.8\mu F$$

where C_{OUTMIN} is the minimum output capacitor(s) required, I_{TRAN} is the transient load current step, and ΔV_{OUT} is the drop in output voltage allowed during the load transient. Choose a capacitor no less than 7.8 μ F for the 48V output. 220 μ F electrolytic capacitor and 18.8 μ F MLCC in total are used for the 48V output.

The output voltage ripple is because of the discontinuous ripple current to the output capacitor and the ESR of the output capacitors as defined by [Equation 15](#).

$$(EQ. 15) \quad V_{RIPPLE} = \left(\frac{(I_{OUT})(V_{OUT})}{V_{INMIN}} + \frac{\Delta I_L}{2} \right) \times ESR = \left(\frac{\left(\frac{3A}{2}\right)(48V)}{12V} + \frac{4.5A}{2} \right) \times 5m\Omega = 41.25mV$$

2.5.9 Input Capacitor Selection

The important parameters for the input capacitors are the voltage rating and the RMS current rating. The capacitor voltage rating should be at least 1.25 times greater than the maximum input voltage and 1.5 times is a conservative guideline.

In Boost mode, the input current is continuous. The RMS current supplied by the input capacitance is noticeably small.

Renesas recommends using a mix of input bypass capacitors to control the voltage ripple across the MOSFETs. Use ceramic capacitors for the high frequency decoupling and bulk capacitors to supply the RMS current. Two 220 μ F electrolytic capacitors with 2.2A rating current and eight 4.7 μ F ceramic capacitors are used to share the input RMS current on this board.

2.5.10 First Level Peak Current Limit and Sense Resistor Selection

The inductor peak current for 48V output is sensed by the shunt resistor R_S (R14). When the voltage drop on R_S reaches the set point $V_{OCSET-CS}$ typical 85mV, it triggers the pulse-by-pulse peak current limit. With the current limit set point $I_{OCPP1} = 1.7 \times I_{INMAX} = 20.4A$ for each phase, the value of the sense resistor is calculated using [Equation 16](#).

$$(EQ. 16) \quad R_S = \frac{V_{OCSET-CS}}{I_{OCPP1}} = \frac{82mV}{20.4A} = 4.02m\Omega$$

Select a standard value resistor $R_S = 4m\Omega$. Then the actual peak current limit is calculated using [Equation 17](#).

$$(EQ. 17) \quad I_{OCPP1} = \frac{V_{OCSET-CS}}{R_S} = \frac{82mV}{4m\Omega} = 20.5A$$

The maximum power dissipation in R_S is calculated using [Equation 18](#).

$$(EQ. 18) \quad P_{RSMAX} = (I_{IN})^2 R_S = (6.14A)^2 (4m\Omega) = 0.15W$$

Therefore, a sense resistor with 1W power rating is sufficient for this application.

2.5.11 Second Level Hiccup Peak Current Protection

In the condition, V_{IN} is so close to V_{OUT} that the inductor current runs away with the minimum on PWM duty. The ISL81805 integrates a second level hiccup type of peak current protection. The second level peak current protection set point I_{OCPP2} is calculated using [Equation 19](#).

$$(EQ. 19) \quad I_{OCPP2} = \frac{V_{OCSET-CS-HIC}}{R_S} = \frac{98mV}{4m\Omega} = 24.5A$$

2.5.12 Input Average Overcurrent Protection and R_{IM} Selection

The ISL81805 provides either constant current or hiccup type of overcurrent protection for input average current. The OCP mode is set by a resistor connected between the LG2/OC_MODE pin and ground. With input constant current/hiccup set point $I_{INOC} = 13.8A$ for 48V output, the current monitoring resistor R_{IM} (R8) is calculated using [Equation 20](#).

$$(EQ. 20) \quad R_{IM} = \frac{1.2}{I_{OUTOC} \times R_S \times G_{m_{CS}} + I_{CSOFFSET}} = \frac{1.2V}{13.8A \times 4m\Omega \times 195\mu S + 20\mu A} = 39.01k\Omega$$

Select a standard value resistor $R_{IM} = 39k\Omega$.

The board can also be configured to be output average overcurrent protection by injecting into the IMON pin an additional signal that changes with V_{IN} . This can be implemented by the resistors R67 and R68, which are between the V_{IN} terminal and the IMON1/IMON2 pins.

2.5.13 PWM Mode Selection

You can set the ISL81805 to either forced PWM mode or DE mode. The mode is set by a resistor $R_{PWMMODE}$ (R30 or R31) connected between the LG1/PWM_MODE pin and GND. The critical resistor value for $R_{PWMMODE}$ is calculated using [Equation 21](#).

$$(EQ. 21) \quad R_{PWMMODE} = \frac{0.3V}{10\mu A} = 30k\Omega$$

A resistor less than 30k Ω sets the converter to forced PWM mode, while a resistor higher than 30k Ω sets the converter to DE mode. Considering the tolerance in all temperature ranges, Renesas recommends using 22k Ω to set to Forced PWM mode and 39k Ω to set to DE mode.

2.5.14 Overcurrent Protection Mode Selection

The ISL81805 is set to either a constant current or hiccup type of overcurrent protection for input average current by selecting a different value of the resistor R_{OCMODE} (R32 or R33) connected between LG2/OC_MODE and GND. The critical resistor value for R_{OCMODE} is calculated using [Equation 22](#).

$$(EQ. 22) \quad R_{OCMODE} = \frac{0.3V}{10\mu A} = 30k\Omega$$

A resistor less than 30k Ω sets the converter to Constant Current mode, while a resistor higher than 30k Ω sets the converter to Hiccup mode. Considering the tolerance in all temperature ranges, Renesas recommends using 22k Ω to set to constant current and 39k Ω to set to hiccup mode.

2.5.15 Phase Lock Loop (PLL)

The PLL of the ISL81805 ensures the wide range of accurate clock frequency and phase setting. It also makes the internal clock easily synchronized to an external clock with the frequency either lower or higher than the internal setting. The external compensation network of R_{PLL} (R20), C_{PLL1} (C27), and C_{PLL2} (C28) is needed to connect to the PLL_COMP pin to ensure PLL stable operation. Renesas recommends choosing 2.7k Ω for R_{PLL} , 10nF for C_{PLL1} , and 820pF for C_{PLL2} .

2.5.16 Feedback Loop Compensation

To adapt the different applications, the controller is designed with an externally compensation network. Figure 13 shows the peak current mode boost converter circuit.

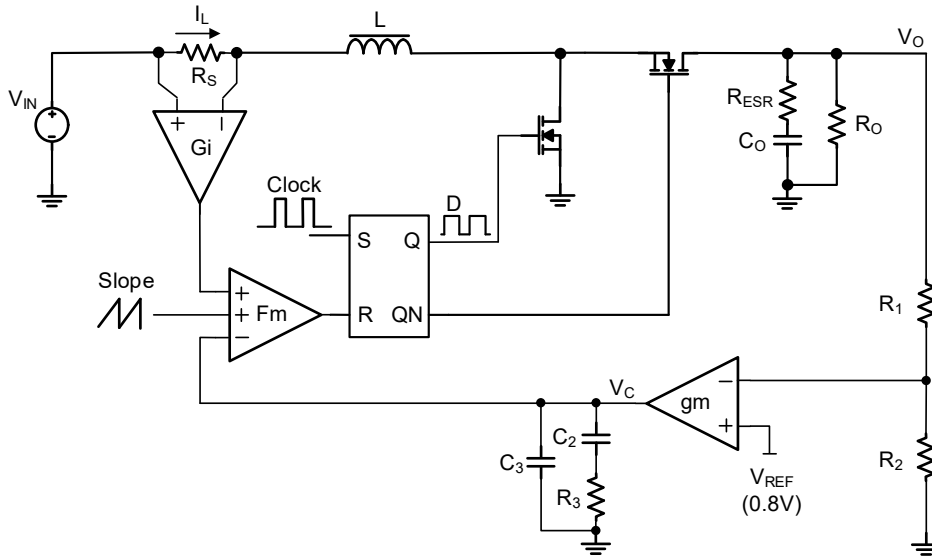

Figure 13. Peak Current Mode Boost Converter Circuit

In the current loop, the control to output simplified transfer function is shown in Equation 23.

$$(EQ. 23) \quad \frac{\hat{V}_O}{\hat{V}_C} = \frac{R_O \times (1-D)}{R_I \times K_d} \times \frac{\left(1 - \frac{s}{\omega_{RHPZ}}\right) \left(1 + \frac{s}{\omega_{z(esr)}}\right)}{\left(1 + \frac{s}{\omega_{po}}\right) \left(1 + \frac{s}{\omega_{pi}}\right)}$$

where:

$$(EQ. 24) \quad K_d = 2 + \frac{R_O \cdot (1-D)^2}{R_I} \cdot \left(\frac{1}{K_m} + \frac{K}{1-D}\right)$$

$$(EQ. 25) \quad K_m = \frac{1}{(D-0.5)R_I \times \frac{T_s}{L} + \frac{V_{SL}}{V_O}}$$

$$(EQ. 26) \quad K = 0.5R_I \times \frac{T_s}{L} \times D \times (1-D)$$

$$(EQ. 27) \quad R_I = G_I \times R_S$$

- R_O is the load resistor
- C_O is the output capacitor
- L is the inductor
- R_S is the current sense resistor
- V_O is the output voltage
- T_s is the period of one switching cycle
- D is the duty cycle of lower MOSFET
- $V_{SL} = 0.843V$, is the slope compensation voltage

- V_{IN} is the input voltage of the boost
- V_C is the output of the error amplifier
- $G_1 = 5.472$, is the gain of the current sensor

The low frequency pole frequency is shown in [Equation 28](#).

$$(EQ. 28) \quad \omega_{p0} = 2\pi f_{p0} = \frac{K_d}{C_o \times R_o}$$

The high frequency pole frequency is shown in [Equation 29](#).

$$(EQ. 29) \quad \omega_{pi} = 2\pi f_{pi} = \frac{K_m \times R_l}{L}$$

The output capacitor ESR (R_{ESR}) zero frequency is shown in [Equation 30](#).

$$(EQ. 30) \quad \omega_{z(esr)} = 2\pi f_{z(esr)} = \frac{1}{C_o \times R_{ESR}}$$

The output voltage is regulated by an error amplifier EA. The EA compensation network parameters can be determined by compensating the current loop poles and zero so as to implement an ideal -20dB/decade close-loop gain with around 1/50~1/20 of f_{SW} crossover frequency.

For boost topology, the maximum crossover frequency is also limited by the RHPZ. Estimate the RHPZ at the minimum input voltage by [Equation 31](#).

$$(EQ. 31) \quad \omega_{RHPZ} = 2\pi f_{RHPZ} = \frac{R}{L} \times (1 - D_{max})^2$$

If the crossover frequency $f_c \ll f_{pi}$, a type-2 compensation network is enough to achieve the goal.

The type-2 EA amplifier transfer function is simplified to [Equation 32](#).

$$(EQ. 32) \quad \frac{\hat{V}_c}{\hat{V}_o} = \frac{R_2}{R_1 + R_2} \cdot g_m \cdot \frac{1 + sR_3C_2}{s(C_2 + C_3) + s^2R_3C_2C_3} = \frac{R_2}{R_1 + R_2} \cdot \frac{g_m}{C_2 + C_3} \cdot \frac{1 + sR_3C_2}{s \left(1 + \frac{sR_3C_2C_3}{C_2 + C_3} \right)}$$

To simplify the model, assuming $C_3 \ll C_2$, the type-2 EA amplifier transfer function is simplified to [Equation 32](#).

$$(EQ. 33) \quad \frac{\hat{V}_c}{\hat{V}_o} = \frac{R_2}{R_1 + R_2} \cdot \frac{g_m}{C_2 + C_3} \cdot \frac{1 + sR_3C_2}{s(1 + sR_3C_3)}$$

where g_m is the gain of error amplifier, typical 1.75mS.

The transfer function has one pole and one zero.

- The pole is at the frequency of $f_{p1} = 1/2\pi R_3 C_3$. This is the frequency where the impedance of R_3 is equal to C_3 .
- The zero is at the frequency of $f_{z1} = 1/2\pi R_3 C_2$. This is the frequency where the impedance of R_3 is equal to C_2 .

To achieve ideal compensation, Renesas recommends making $f_{z1} = f_{p0}$ and $f_{p1} = f_{z(esr)}$ as shown in [Figure 14](#).

Figure 14. Feedback Loop Compensation

The close-loop transfer function is then simplified to Equation 34.

$$(EQ. 34) \quad G_{loop}(s) = \frac{R_O \times (1-D)}{R_I \times K_d} \times \frac{\left(1 - \frac{s}{\omega_{RHPZ}}\right) \left(1 + \frac{s}{\omega_{z(esr)}}\right)}{\left(1 + \frac{s}{\omega_{p0}}\right) \left(1 + \frac{s}{\omega_{pi}}\right)} \times \left(-\frac{R_2}{R_1 + R_2} \cdot \frac{g_m}{C_2 + C_3}\right) \cdot \frac{1 + sR_3C_2}{s(1 + sR_3C_3)}$$

The Loop design example for the 48V output under 20V input voltage is shown in the following:

$V_{IN} = 20V$, $V_{OUT} = 48V$, $I_{OUT} = 3A$, $f_{sw} = 200kHz$, $T_s = 5\mu s$, $D = 1 - V_{IN} / V_{OUT} = 0.588$, $L = 10\mu H$, $C_O = 238.8\mu F$ ($220\mu F + 4.7\mu F \times 4$), $R_O = V_{OUT} / I_{OUT} = 16\Omega$, $R_s = 4m\Omega$, $R_{esr} = 10m\Omega$.

$$(EQ. 35) \quad K_m = \frac{1}{(D-0.5)R_I \times \frac{T_s}{L} + \frac{V_{SL}}{V_O}} = \frac{1}{(0.588-0.5)(4m\Omega \times 5.472) \times \frac{5\mu s}{10\mu H} + \frac{0.843V}{48V}} = 53.98$$

$$(EQ. 36) \quad K_d = 2 + \frac{R_O \cdot (1-D)^2}{R_I} \cdot \left(\frac{1}{K_m} + \frac{K}{1-D}\right) = 2 + \frac{16 \cdot (1-0.588)^2}{4m\Omega \times 5.472} \cdot \left(\frac{1}{53.98} + 0.5 \times 4m\Omega \times 5.472 \times \frac{5\mu s}{10\mu H} \times 0.588\right) = 4.7$$

$$(EQ. 37) \quad \omega_{p0} = \frac{K_d}{C_O \times R_O} = \frac{4.7}{238.8\mu F \times 16\Omega} = 1.23kHz$$

$$(EQ. 38) \quad f_{p0} = \frac{\omega_{p0}}{2\pi} = 0.196kHz$$

$$(EQ. 39) \quad \omega_{pi} = \frac{K_m \times R_I}{L} = \frac{53.98 \times 0.022\Omega}{10\mu H} = 118.8kHz$$

$$(EQ. 40) \quad f_{pi} = \frac{\omega_{pi}}{2\pi} = 18.9kHz$$

$$(EQ. 41) \quad \omega_{z(esr)} = \frac{1}{C_O \times R_{ESR}} = \frac{1}{238.8\mu F \times 10m\Omega} = 418.8kHz$$

$$(EQ. 42) \quad f_{z(esr)} = \frac{\omega_{z(esr)}}{2\pi} = 66.66kHz$$

The minimum value of RHPZ can be calculate using Equation 43.

$$(EQ. 43) \quad f_{RHPZ} = \frac{R_O}{2\pi \times L} \times (1 - D_{max})^2 = \frac{16\Omega}{2\pi \times 10\mu H} \times \left(\frac{12V}{48V}\right)^2 = 15.92kHz$$

Therefore, make $0.1 \times f_{RHPZ}$ as crossover frequency and make the gain -20dB/decade:

$$(EQ. 44) \quad f_c = 0.1 \times f_{RHPZ} = 1.59kHz$$

If R_3 (R18) = 10k, set the frequency of this zero $f_{z1} = f_{p0}$, then C_2 (C17) is calculated using Equation 45.

$$(EQ. 45) \quad C_2 = \frac{1}{2\pi R_3 f_{p0}} = \frac{1}{2\pi \times 10k\Omega \times 0.196kHz} = 81.2nF$$

Select a standard value capacitor C_2 (C17) = 82nF.

Set the frequency of this pole $f_{p1} = f_{z(esr)}$, and should make sure $f_c \ll f_{p1} \ll f_{sw}$. Then C_3 (C15) is calculated using Equation 46.

$$(EQ. 46) \quad C_3 = \frac{1}{2\pi R_3 f_{z(esr)}} = \frac{1}{2\pi \times 10k\Omega \times 66.66kHz} = 238.8pF$$

Select a standard value capacitor C_3 (C15) = 220pF.
