Introduction

The CC1050 single chip transmitter includes many features and great flexibility, which makes the chip suitable for a very large number of applications and system requirements. The CC1050DK Development Kit is designed to make it very easy for the user to evaluate transmitter performance and in short time develop his own applications.

The Development Kit includes one evaluation board with a complete CC1050 transmitter, voltage regulator and PC interface circuitry. Using the evaluation board connected to a PC running the SmartRF[®] Studio software, various system parameters can be changed and tested by keystrokes.

Technical features:

- RF power up to 12/8 dBm (433/868 MHz) programmable in 1 dB steps
- Logic level data input (Manchester coded or NRZ)
- Logic level synchronisation clock output
- All set-up controlled by PC
- Selectable 3 V or 4-10 V unregulated voltage supply inputs

This user manual describes how to get started with the Development Kit. You will also find detailed description of the evaluation board and advice how to develop your own applications. For details on how to use the SmartRF[®] Studio software please refer to the SmartRF[®] Studio User Manual.

Your SmartRF[®] CC1050DK Development Kit should contain the following items:

Kit contents	
Item	Number of articles
Evaluation Board (CC5000EB)	1
PC parallel port extension cable (25-pin D-sub, male-female, 3m)	1
Adapter(SMA male-BNC female)	3
Antenna (50Ω, λ/4 monopole, SMA male)	1
Quick Start User Manual	1
CC1050 sample kit	1

The evaluation board includes a significant number of components for great flexibility. However, only a minor part of these components are required in an actual application. Check the datasheet for a typical application circuit.

Evaluation Board

The kit includes an Evaluation Board (CC1050EB) with the following items:

- A SmartRF[®] CC1050 chip.
- Necessary external surface mounted devices, SMDs, for the chip.
- Voltage regulator 4 –10 V to 3V regulated voltage.
- Possibilities to apply a 3 V voltage source directly (chosen by the switch on the board).
- Voltage-level interface circuits between the CC1050 chip (3 V) and the parallel port of the computer (5 V).
- Connector for a PC parallel port cable.
- Connector for antenna, modulation data in and synchronisation clock out.
- Pin connector for interfacing to MCU

This board is designed for great flexibility so that you can evaluate the circuit performance for several circuit configurations, and in development of your own applications. The evaluation board is distributed in two versions, and the difference is the frequency band of operation. The two versions are optimised for 433 MHz and 868 MHz to cover the two licence free band in Europe. The operating frequency band is marked on the Evaluation Board.

Description

The evaluation circuit board constitutes of three main parts. These are the RF-section, the voltage supply and the PC-interface. The PC-interface contains voltage level shift circuit, which buffers the control lines.

Voltage supply

You can chose between applying a 4-10 V non-regulated supply voltage or a 3 V regulated supply voltage by setting a switch on the board (SPDT). If a non-regulated supply voltage is applied, an on board regulator generates a regulated 3 V supply. A diode prevents damage if wrong polarity is used for the non-regulated input. The connector has five contacts, which is shown below. In addition to the three supply voltage contacts, there are two contacts, which can be used to measure the DC current to the CC1050 chip. A short jumper is placed between these two contacts for the circuit to work. If you want to measure the DC current, replace the jumper with an amperemeter (as shown in the figure below). The current range is from 0 to 26 mA.

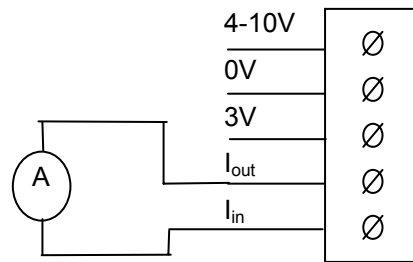

Figure 1: The power connector with an amperemeter attached.

RF-section

The RF section consists of a CC1050 chip with external components. The different components are explained below.

The loop filter

The CC1050 has integrated the loop-filter and shaping features on-chip. For flexibility it is also possible to use an external loop-filter. The PLL loop filter contains the components C5-C6 and R2. However, in most cases the internal filter will give the optimum performance. The loop filter is connected to the same pin as the monitoring of the lock indicator. When external loop-filter is added, the R80 must be removed to avoid conflict with the lock line connected to the parallel port.

The LOCK signal

A LOCK signal is connected to the parallel port interface to be monitored by the software. The signal tells you if the synthesiser frequency is in lock. It is also available at P4, and is active high.

This digital output can also be configured to other functions, as control signal for external PA. Please see the data sheet for details.

Note: To monitor this signal CC1050 must be configured to take out this signal on CHP_OUT. This is the default setting of SmartRF Studio. If external loop filter is added the lock signal cannot be used due to the loop filter is connected to the same pin.

DI and DCLK

The modulation input (DI) and the synchronisation output (DCLK) is connected to separate connectors. The connectors are of SMA female type. The data to be sent can be of either Manchester or NRZ. The Manchester code ensures that the signal has no DC component. The Manchester code is based on transitions; a "0" is encoded as a low-to-high transition, a "1" is encoded as a high-to-low transition. See figure below. Maximum data-rate is 38.4 kbit/s

giving a baud rate of 76.8 kbaud that is chosen in the software. For NRZ the baud rate is equal to the bit rate and is maximum 76.8 kbit/s.

Please have in mind that the DI line must be of NRZ format even for Manchester mode selection. The encoding to Manchester is in this mode done internally by CC1050.

The CC1050 has an internal clock synchronisation circuit that can be monitored on DCLK. The relationship between DI and DCLK is given in the CC1050 data sheet.

PA matching

The output-matching network is optimised for either 433 MHz or 868 MHz operation. The component values are calculated in the software program, and consist of L2, C1 and C2. Using the specified component values for the output match will give an optimum match at the specified operating frequency. Minor tuning of the component values may be necessary to compensate for layout parasitics at other frequencies or other layouts. A T-type LC-filter is used for reducing the harmonics. See Application note AN028 *Improved LC-filter* for details.

The crystal oscillator

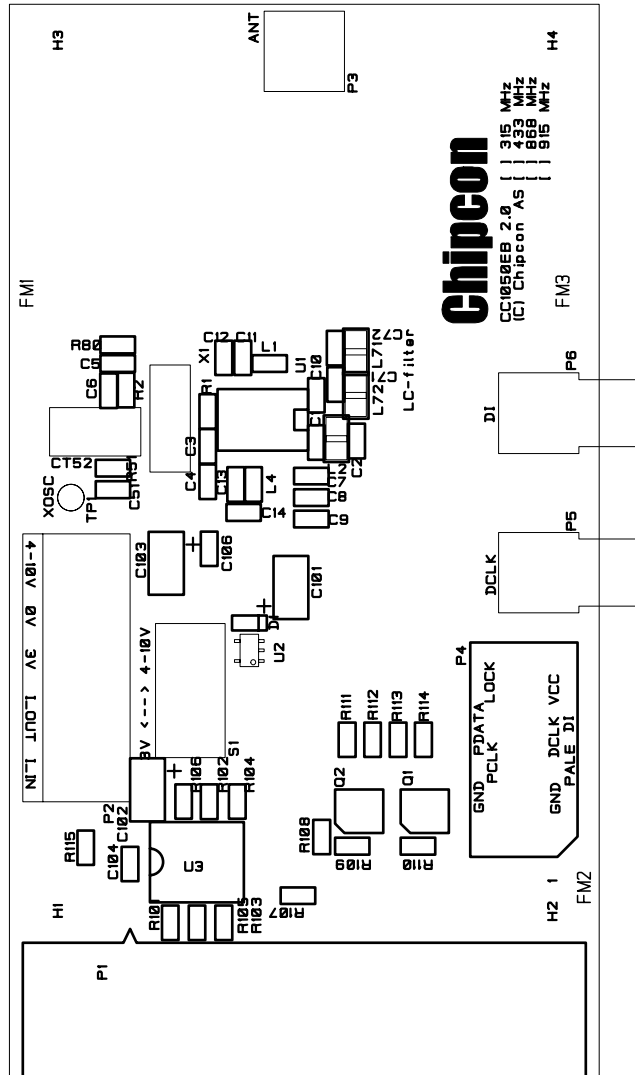

The crystal frequency, X1, is set to 14.7456 MHz. The crystal oscillator circuit has a trimmer capacitor, CT52, which reduces the initial tolerance of the crystal to zero by careful adjustment using a precision frequency counter. The crystal used at this board has ± 10 ppm accuracy and ± 10 ppm over the -10 to $+70$ °C temperature range. The crystal oscillator has an AC coupled (C51) test pin for external clock injection, TP1. Be sure to remove the crystal when an external clock is used. The external clock should have amplitude of 1-3 V_{pp}. The loading capacitors are designed for a 16 pF crystal load.

Using the Development Kit

The purpose of the Development Kit is to give users of the integrated transmitter CC1050 hands-on experience with the chip. A typical set-up of the evaluation board is shown below. The evaluation board is connected to a PC to be programmed by the SmartRF Studio software. You can also easily connect your MCU to the 10-pin connector P4, and implement prototype software without doing hardware design. R111-R113 should be removed when connecting your MCU to P4.

The data signal that you want to send in transmit mode can be of either Manchester or NRZ code. A square wave from a function generator can be used to generate this data. The signal source shall be connected to the Data I/O port (DI) at the evaluation board. The signal must be a square wave from 0 to 3V as shown. Do not apply a 5V signal because it can damage the CC1050 chip. The signal from the function generator will represent either zeroes or ones, and the bit rate in Manchester coded will be $1/T$, where T is the period time. For the NRZ case, the bit rate is given by $2/T$ due to the fact that the bit rate is equal to the baud rate in NRZ.

The transmitted signal can be studied on a spectrum analyser, sent out on the antenna (see note below).

Figure 2: Equipment set-up in transmit mode.

Important: The use of radio transmitters is regulated by international and national rules. Before transmitting a RF signal out on the antenna, please contact your local telecommunication authorities to check if you are licensed to operate the transmitter.
