# LOW-VOLTAGE 10-BIT BUS SWITCH WITH PRECHARGED OUTPUTS

### 74CBTLV6800

### **FEATURES:**

- Functionally equivalent to QS3800
- $5\Omega$  A/B bi-directional switch
- · Isolation under power-off conditions
- · Over-voltage tolerant
- · Latch-up performance exceeds 100mA
- Vcc = 2.3V 3.6V, Normal Range
- ESD > 2000V per MIL-STD-883, Method 3015;
  > 200V using machine model (C = 200pF, R = 0)
- · Available in QSOP and TSSOP packages

#### **APPLICATIONS:**

· 3.3V High Speed Bus Switching and Bus Isolation

# DESCRIPTION:

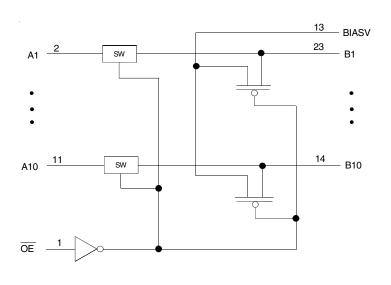

The CBTLV6800 provides 10-bits of high-speed bus switching with low on-state resistance of the switch allowing connections to be made with minimal propagation delay. The device also precharges the B port to a user-selectable bias voltage (BIASV) to minimize live-insertion noise.

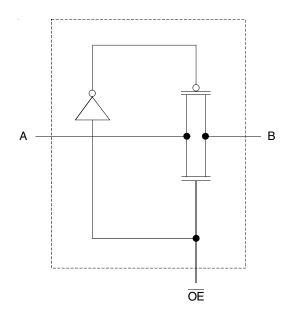

The CBTLV6800 is organized as a single 10-bit bus switch with a single output-enable  $(\overline{OE})$  input. When  $\overline{OE}$  is low, the 10-bit bus switch is on and port A is connected to port B. When  $\overline{OE}$  is high, the switch is open, and a high impedance state exists between the two ports, and port B is precharged to BIASV through the equivalent of a 10-k $\Omega$  resistor.

 $\overline{OE}$  should be tied to VCC through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver.

#### NOTE:

1. Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

**INDUSTRIALTEMPERATURE RANGE** 

#### NOTES:

- 1. The increase in supply current is attributable to each current that is at the specified voltage level rather than Vcc or GND.
- 2. This is measured by the voltage drop between the A and B terminals at the indicated current through the switch. On-state resistance is determined by the lower of the voltages of the two (A or B) terminals.
