Self Protected High Side Driver with Temperature Shutdown and Current Limit

The NCV8445 is a fully protected High–Side driver that can be used to switch a wide variety of loads, such as bulbs, solenoids and other acuators. The device is internally protected from an overload condition by an active current limit and thermal shutdown.

A diagnostic output reports ON and OFF state open load conditions as well as thermal shutdown.

Features

- Short Circuit Protection
- Thermal Shutdown with Automatic Restart
- CMOS (3.3 V / 5 V) compatible control input
- Open Load Detection in On and Off State
- Diagnostic Output
- Undervoltage and Overvoltage Shutdown
- Loss of Ground Protection
- ESD protection
- Slew Rate Control for Low EMI Switching
- Very Low Standby Current
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These Devices are Pb-Free and are RoHS Compliant

Typical Applications

- Switch a Variety of Resistive, Inductive and Capacitive Loads
- Can Replace Electromechanical Relays and Discrete Circuits
- Automotive / Industrial

Not subjected to production testing
 To ensure long term reliability under heavy overload or short circuit conditions, protection and related diagnostic signals must be used together with a proper hardware/software strategy. If the devices operates under abnormal conditions this hardware/software solutions must limit the duration and number of activation cycles.

Class	Functional Status
Α	All functions of a device perform as designed during and after exposure to disturbance.
В	All functions of a device perform as designed during exposure. However, one or more of
	them can go beyond specified tolerance. All functions return automatically to within normal
	limits after exposure is removed. Memory functions shall remain class A.
С	One or more functions of a device do not perform as designed during exposure but return
	automatically to normal operation after exposure is removed.
D	One or more functions of a device do not perform as designed during exposure and do not return to normal operation until exposure is removed and the device is reset by simple
E	One or more functions of a device do not perform as designed during and after exposure and cannot be returned to proper operation without replacing the device.

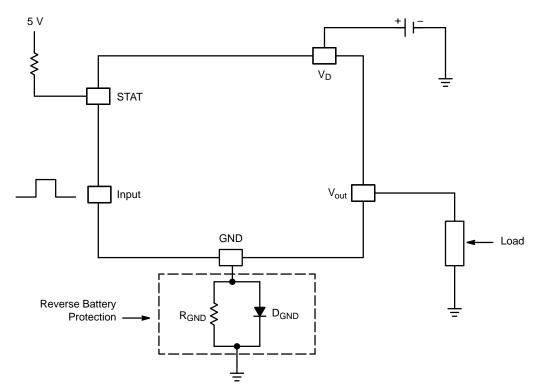

Figure 31. Application Diagram

Reverse Battery Protection

An external resistor R_{GND} is required to adequately protect the device from a Reverse Battery event. The resistor value can be calculated using the following two formulas.

- 1. $R_{GND} \ge 600 \text{ mV} / (I_d \text{ (on) max})$
- 2. $R_{GND} \ge (-V_D) / (-I_{gnd})$

Maximum (- I_{gnd}) current, which is the reverse GND pin current, can be found in the Maximum Ratings section. Several High Side Devices can share same the reverse battery protection resistor. Please note that the sum of (I_d (on) max) of all devices should be used to calculate R_{GND} value. If the microprocessor ground is not common with the device ground, R_{GND} will produce a voltage offset ((I_d (on) max) x R_{GND}) with respect to the IN and STAT pins.

This offset will be increased when more than one device shares the resistor.

Power Dissipation during a reverse battery event is equal to:

$$P_{D} = \left(-V_{D}\right)^{2} / R_{GND}$$

In the case of high power dissipation due to several devices sharing R_{GND} , it is recommended to place a diode D_{GND} in the ground path as an alternate reverse battery protection method. When driving an inductive load, a 1 $k\Omega$ resistor should be placed in parallel with the D_{GND} diode. This method will also produce a voltage offset of ~600 mV with respect to the IN and STAT pins. This diode can also be shared amongst several High Side Devices. This voltage offset will vary if D_{GND} is shared by multiple devices.

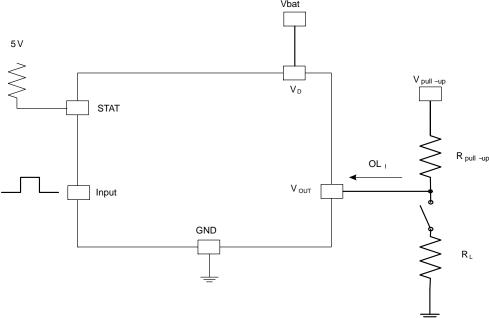

Figure 32. Open Load Detection In Off State

OFF State Open Load Detection

Off State Open Load Detection requires an external pull-up resistor ($R_{pull-up}$) connected between V_{OUT} pin and a positive supply voltage ($V_{pull-up}$).

The external $R_{pull-up}$ resistor value should be selected to ensure that a false OFF State OL condition is not detected when the load (R_L) is connected. A V_{OUT} voltage above the V_{OL_min} (Openload Off State Detection Threshold) minimum value with the load (R_L) connected needs to be avoided. The following formula shows this relationship:

$$V_{OUT} = \left(V_{pull-up}/\left(R_L + R_{pull-up}\right)\right)R_L < V_{OL_min}$$

In addition to ensuring the selected $R_{pull-up}$ resistor value does not cause a false OFF State OL detection condition

when the load is connected, the $R_{pull-up}$ must also not cause the OFF State OL to miss detecting an OL condition when the load is disconnected. A V_{OUT} voltage below the V_{OL_max} (Openload Off State Detection Threshold) maximum value with the load (R_L) disconnected needs to be avoided. The following formula shows this relationship:

$$R_{pull-up} < (V_{pull-up} - V_{OL\ max})/OL_1$$

$$OL_1 = I_L (Output Leakage with V_{OUT} = 3.5 V)$$

Because I_d (OFF) may significantly increase if V_{OUT} is pulled high (up to several mA), $R_{pull-up}$ resistor should be connected to a supply that is switched OFF when the module is in standby.
