## Single Chip PAL

## Luminance/Chroma Processor

May 1997

### Features

- All PAL Luminance and Chrominance Processing Circuitry on a Single Chip in a 24-Lead Plastic Package
- Phase-Locked Subcarrier Regeneration Utilizing Sample-and-Hold
- DC Controls for Brightness, Contrast, and Color Saturation Functions
- Input for Average Beam-Current Limiting
- Contrast Control Having Excellent Tracking of Luma and Chroma Channels
- Low-Impedance RGB Outputs with Excellent Tracking for Direct Coupling to Video Driver Circuitry

### Description

The Harris CA3194E is a silicon monolithic integrated circuit designed to perform all of the signal processing functions for both the chroma and luminance signals of PAL color television receivers.

This circuit performs all the functions needed between the video detector and the video RGB output stages. DC contrast, brightness, and saturation controls and average beam limiting functions are included. The RGB buffer stages are capable of delivering 5mA of current into the video output stages.

NOTE: Formerly Dev. No. TA10313.

**NOTES:**

1. If a different value is desired, see the Threshold Adjustment Circuit of Figure 17.
2. Use of the circuit of Figure 18 is suggested to prevent increased color saturation at low level RF signals.
3. The reference voltage can be adjusted by changing the values of the voltage divider.

**Circuit Description** (See Block Diagram and Figure 20)

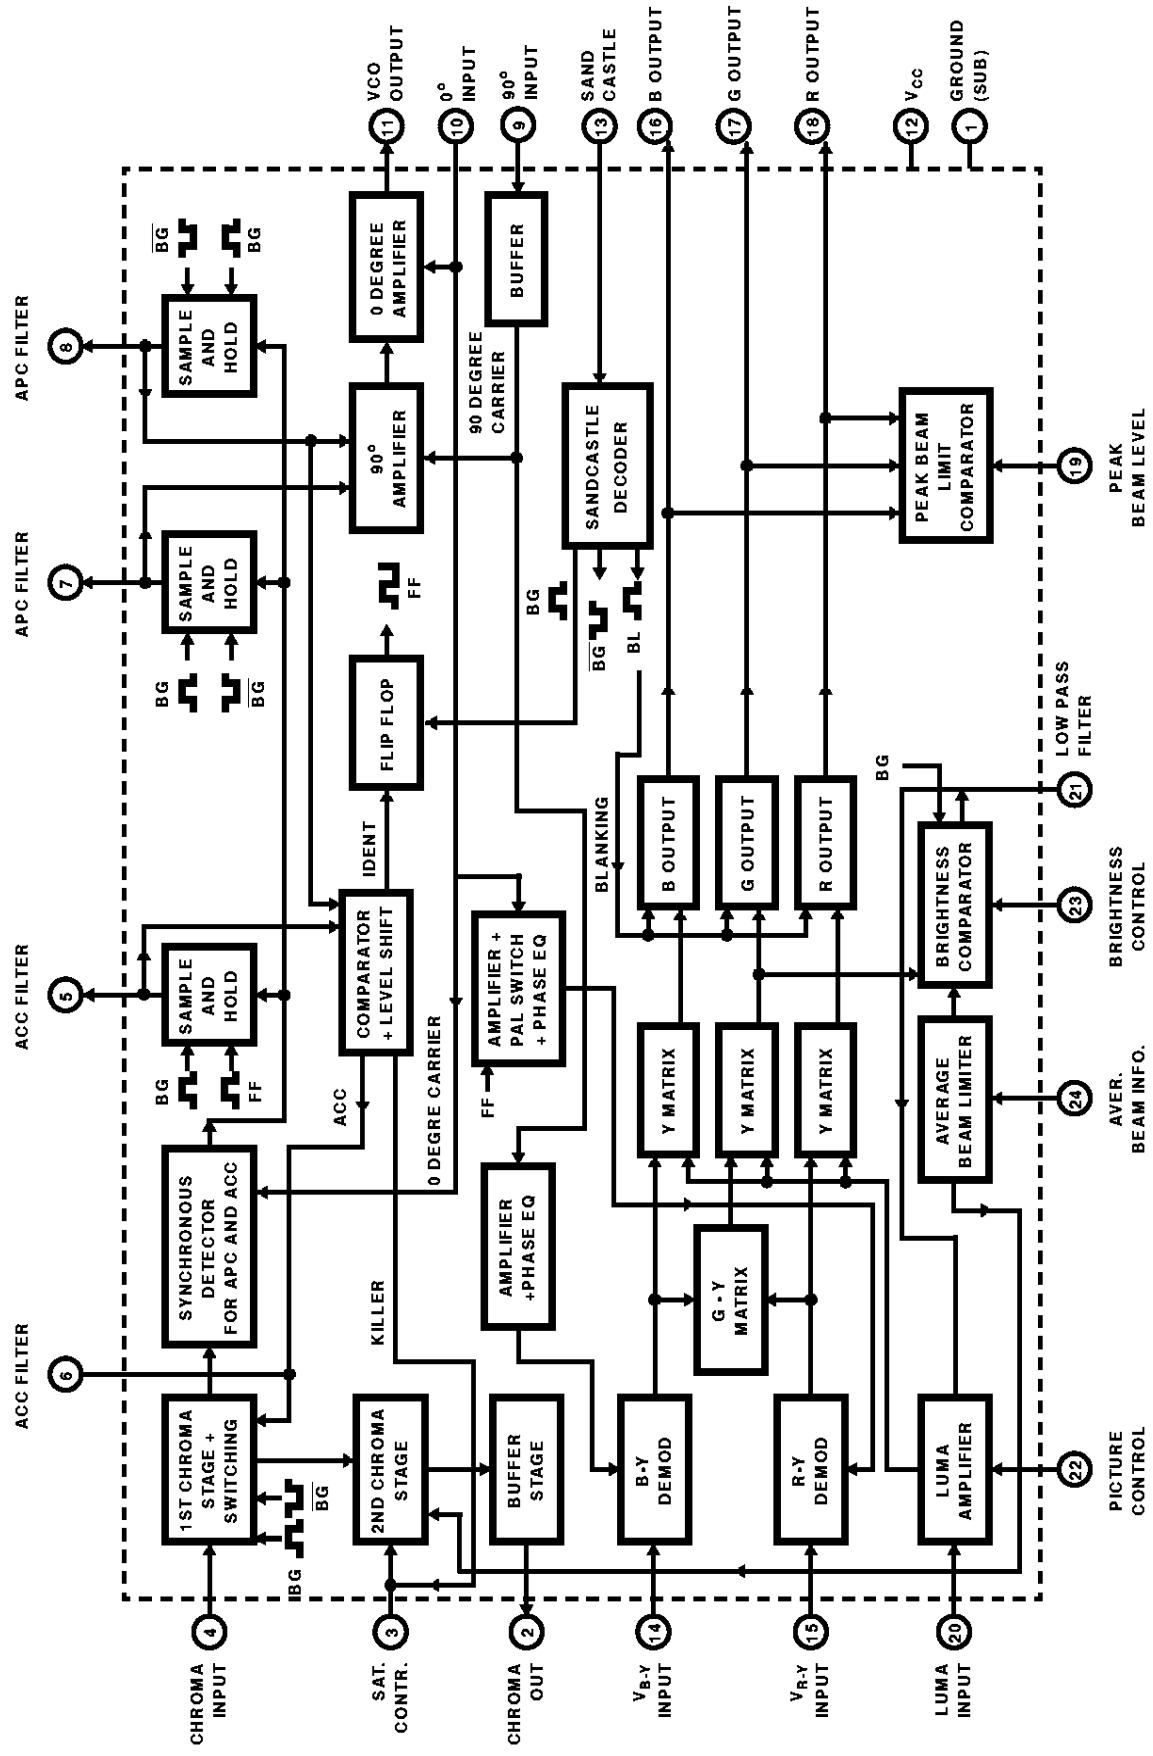

The chroma signal is externally separated from the video signal by means of a bandpass or high-pass filter and applied to pin 4. The burst is separated in the first chroma stage and applied to the synchronous detector which provides information to sample-and-hold circuits for APC (phase-locked loop), ACC (automatic chroma gain control) and identification and killing. The 4.43MHz crystal oscillator is phase-locked to the burst and provides 0 degrees and 90 degrees (via an external phase shifter) carriers to the chroma demodulators. The burst and chroma amplitude at the output of the first chroma amplifier is kept constant by the automatic gain control.

The second chroma stage provides saturation control (pin 3) which tracks the contrast control in the luminance channel. This stage is also used for color killing.

A buffer stage drives the external PAL delay line. The separated U and V signals are applied to pins 14 and 15, respectively, and demodulated. A standard G-Y matrix is included on the chip.

The luminance signal passes through the subcarrier trap and through the luminance delay line and enters the chip at pin 20. Contrast and brightness control is provided before the luminance signal is combined with the color difference signals in the Y matrix. Average and peak beam limiting circuits are controlled from pins 24 and 19.
