LOW-NOISE, HIGH-SPEED, CURRENT FEEDBACK AMPLIFIERS

Check for Samples: THS3112, THS3115

FEATURES

- **Low Noise:**
  - **2.9-pA/√Hz Noninverting Current Noise**
  - **10.8-pA/√Hz Inverting Current Noise**
  - **2.2-nV/√Hz Voltage Noise**
- **Wide Supply Voltage Range: ±5 V to ± 15 V**
- **Wide Output Swing:**
  - **25-V_{PP} Output Voltage, R_L = 100 Ω, ±15-V Supply**
- **High Output Current: 150 mA (Min)**
- **High Speed:**
  - **110-MHz (–3-dB BW, G = 1, ±15 V)**
  - **1550-V/µs Slew Rate (G = 2, ±15 V)**
- **Low Distortion (G = 2):**
  - **–78 dBc (1 MHz, 2 V_{PP}, 100-Ω Load)**
- **Low-Power Shutdown (THS3115)**
  - **300-µA Shutdown Quiescent Current per Channel**
- **Standard SOIC, SOIC PowerPAD™, and TSSOP PowerPAD Packages**
- **Evaluation Module Available**

APPLICATIONS

- **Communication Equipment**
- **Video Distribution**
- **Motor Drivers**
- **Piezo Drivers**

DESCRIPTION

The THS3112/5 are low-noise, high-speed current feedback amplifiers, ideal for any application requiring high output current. The low noninverting current noise of 2.9 pA/√Hz and the low inverting current noise of 10.8 pA/√Hz increase signal-to-noise ratios for enhanced signal resolution. The THS3112/5 can operate from ±5-V to ±15-V supply voltages, while drawing as little as 4.5 mA of supply current per channel. It offers low –78-dBc total harmonic distortion driving 2 V_{PP} into a 100-Ω load. The THS3115 features a low-power shutdown mode, consuming only 300-µA shutdown quiescent current per channel. The THS3112/5 are packaged in standard SOIC, SOIC PowerPAD™, and TSSOP PowerPAD packages.

VOLTAGE NOISE AND CURRENT NOISE vs FREQUENCY

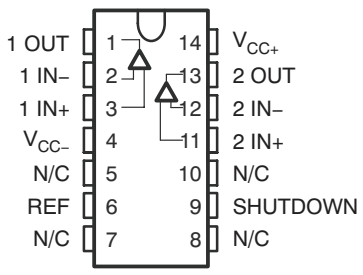
THS3115 SOIC (D) AND TSSOP PowerPAD™ (PWP) PACKAGE (TOP VIEW)



This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

ABSOLUTE MAXIMUM RATINGS(1)

Over operating free-air temperature (unless otherwise noted).

		UNIT
Supply voltage, V_{CC+} to V_{CC-}		33 V
Input voltage		$\pm V_{CC}$
Output current (see (2))		275 mA
Differential input voltage		±4 V
Maximum junction temperature		+150°C
Total power dissipation at (or below) +25°C free-air temperature		See Dissipation Ratings Table
Operating free-air temperature, T_A	Commercial	0°C to +70°C
	Industrial	–40°C to +85°C
Storage temperature, T_{stg}	Commercial	–65°C to +125°C
	Industrial	–65°C to +125°C

(1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

(2) The THS3122 and THS3125 may incorporate a PowerPAD™ on the underside of the chip. This pad acts as a heatsink and must be connected to a thermally dissipating plane for proper power dissipation. Failure to do so may result in exceeding the maximum junction temperature which could permanently damage the device. See TI Technical Brief SLMA002 for more information about utilizing the PowerPAD™ thermally-enhanced package.

DISSIPATION RATINGS TABLE

PACKAGE	θ_{JA}	T_A = +25°C POWER RATING
D-8	95°C/W(1)	1.32 W
DDA	67°C/W	1.87 W
D-14	66.6°C/W(1)	1.88 W
PWP	37.5°C/W	3.3 W

(1) These data were taken using the JEDEC proposed high-K test PCB. For the JEDEC low-K test PCB, the θ_{JA} is 168°C/W for the D-8 package and 122.3°C/W for the D-14 package.

RECOMMENDED OPERATING CONDITIONS

		MIN	NOM	MAX	UNIT
Supply voltage, V_{CC+} to V_{CC-}	Dual supply	±5		±15	V
	Single supply	10		30	
Operating free-air temperature, T_A	C-suffix	0		+70	°C
	I-suffix	–40		+85	

ELECTRICAL CHARACTERISTICS

Over operating free-air temperature range, T_A = +25°C, V_{CC} = ±15 V, R_F = 750 Ω, and R_L = 100 Ω (unless otherwise noted).

DYNAMIC PERFORMANCE

PARAMETER		TEST CONDITIONS			MIN	TYP	MAX	UNIT

APPLICATION INFORMATION

Maximum Slew Rate for Repetitive Signals

The THS3115 and THS3112 are recommended for high slew rate pulsed applications where the internal nodes of the amplifier have time to stabilize between pulses. It is recommended to have at least a 20-ns delay between pulses.

The THS3115 and THS3112 are not recommended for applications with repetitive signals (sine, square, sawtooth, or other) that exceed 900 V/µs. Using the part in these applications results in excessive current draw from the power supply and possible device damage.

For applications with high slew rate, repetitive signals, the THS3091 and THS3095 (single versions), or THS3092 and THS3096 (dual versions) are recommended.

Wideband, Noninverting Operation

The THS3115 and THS3112 are unity gain stable 100-MHz current-feedback operational amplifiers, designed to operate from a ±5-V to ±15-V power supply.

Figure 39 shows the THS3115 in a noninverting gain of 2-V/V configuration used to generate the typical characteristic curves. Most of the curves were characterized using signal sources with 50-Ω source impedance and with measurement equipment that presents a 50-Ω load impedance.

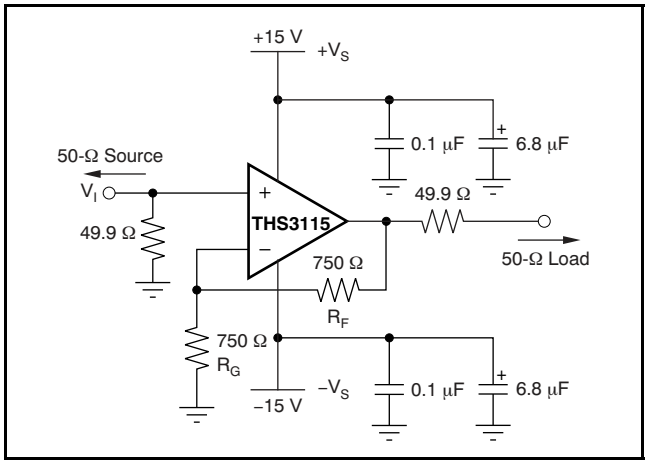

Figure 39. Wideband, Noninverting Gain Configuration

Current-feedback amplifiers are highly dependent on the feedback resistor R_F for maximum performance and stability. Table 1 shows the optimal gain setting resistors R_F and R_G at different gains to give maximum bandwidth with minimal peaking in the frequency response. Higher bandwidths can be achieved, at the expense of added peaking in the frequency response, by using even lower values for R_F. Conversely, increasing R_F decreases the bandwidth, but stability is improved.

Table 1. Recommended Resistor Values for Optimum Frequency Response

THS3115 and THS3112 R_F and R_G VALUES FOR MINIMAL PEAKING WITH R_L = 50 Ω, ±5-V to ±15-V POWER SUPPLY		
GAIN (V/V)	R_G (Ω)	R_F (Ω)
1	—	1 k
2	750	750
4	187	560
8	28.7	200
–1	750	750
–4	140	560
–8	53.6	430

Wideband, Inverting Operation

Figure 40 shows the THS3115 in a typical inverting gain configuration designed for 50-Ω input/output.

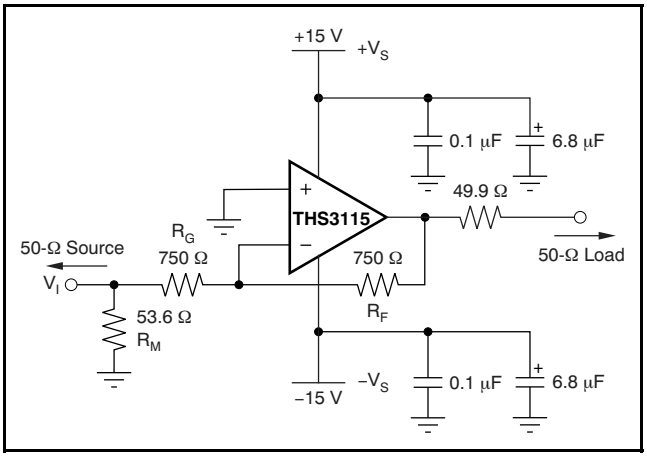

Figure 40. Wideband, Inverting Gain Configuration

Single-Supply Operation

The THS3115 and THS3112 have the capability to operate from a single supply voltage ranging from 10 V to 30 V. When operating from a single power supply, biasing the input and output at mid-supply allows for the maximum output voltage swing. The circuits in Figure 41 show inverting and noninverting amplifiers configured for single-supply operation.

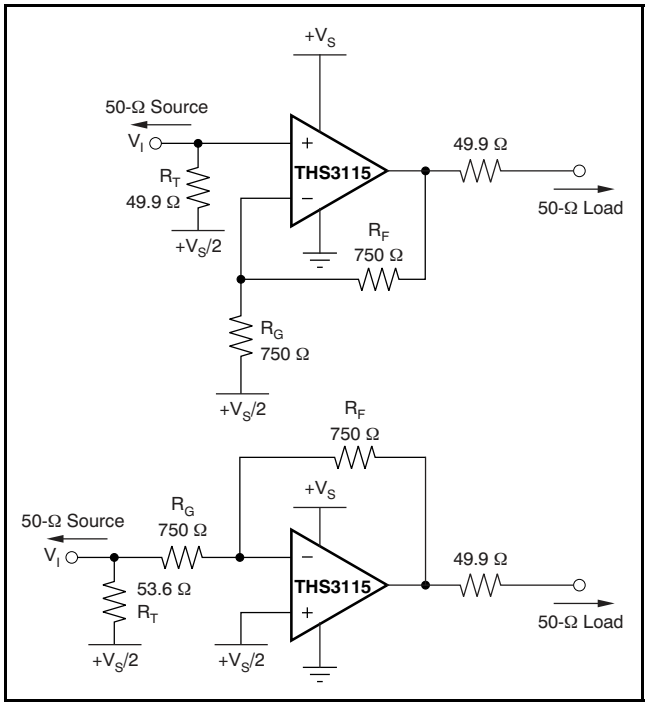

Figure 41. DC-Coupled, Single-Supply Operation

Video Distribution

The wide bandwidth, high slew rate, and high output drive current of the THS3115 and THS3112 match the demands for video distribution to deliver video signals down multiple cables. To ensure high signal quality with minimal degradation of performance, a 0.1-dB gain flatness should be at least 7x the passband frequency to minimize group delay variations from the amplifier. A high slew rate minimizes distortion of the video signal, and supports component video and RGB video signals that require fast transition times and fast settling times for high signal quality. Figure 42 illustrates a typical video distribution amplifier application configuration.

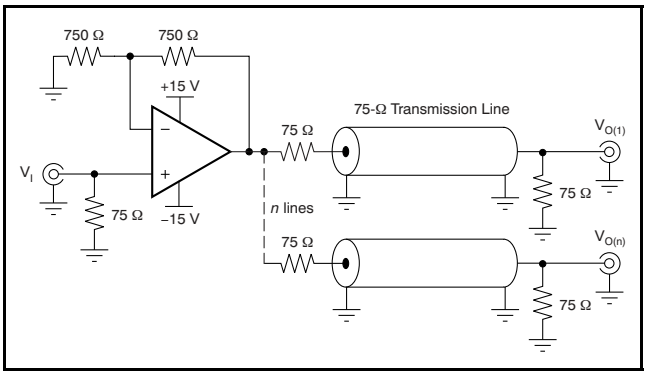

Figure 42. Video Distribution Amplifier Application

Driving Capacitive Loads

Applications such as FET drivers and line drivers can be highly capacitive and cause stability problems for high-speed amplifiers.

Figure 43 through Figure 49 show recommended methods for driving capacitive loads. The basic idea is to use a resistor or ferrite chip to isolate the phase shift at high frequency caused by the capacitive load from the amplifier feedback path. See Figure 43 for recommended resistor values versus capacitive load.

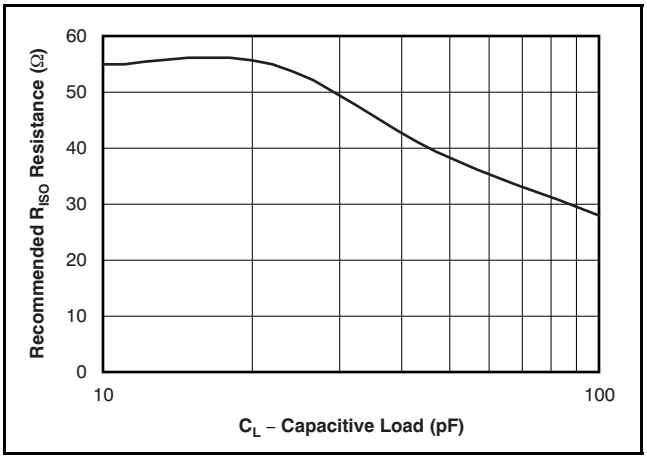

Figure 43. Recommended R_{ISO} vs Capacitive Load

Placing a small series resistor, R_{ISO}, between the amplifier output and the capacitive load, as shown in Figure 44, is an easy way of isolating the load capacitance.

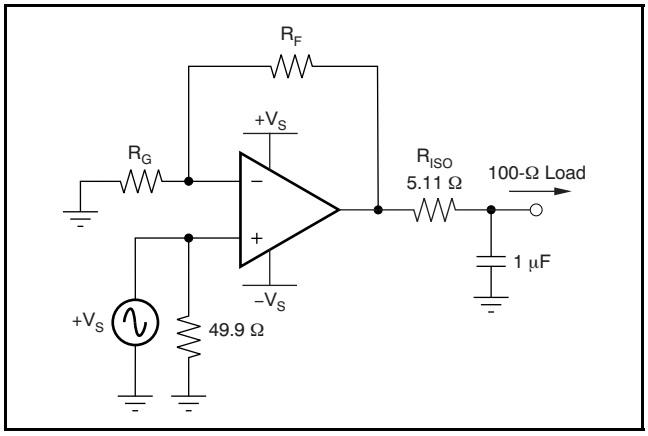

Figure 44. Resistor to Isolate Capacitive Load

Using a ferrite chip in place of R_{ISO}, as Figure 45 shows, is another approach of isolating the output of the amplifier. The ferrite impedance characteristic versus frequency is useful to maintain the low frequency load independence of the amplifier while isolating the phase shift caused by the capacitance at high frequency. Use a ferrite with similar impedance to R_{ISO}, 20 Ω to 50 Ω, at 100 MHz and low impedance at dc.

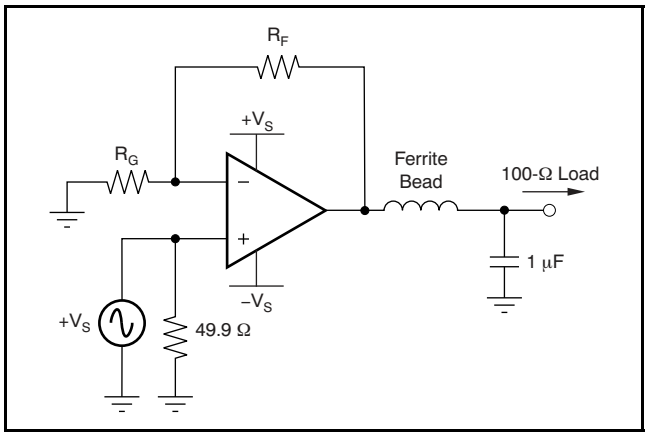

Figure 45. Ferrite Bead to Isolate Capacitive Load

Figure 46 shows another method used to maintain the low-frequency load independence of the amplifier while isolating the phase shift caused by the capacitance at high frequency. At low frequency, feedback is mainly from the load side of R_{ISO}. At high frequency, the feedback is mainly via the 27-pF capacitor. The resistor R_{IN} in series with the negative input is used to stabilize the amplifier and should be equal to the recommended value of R_F at unity gain. Replacing R_{IN} with a ferrite of similar impedance at about 100 MHz as shown in Figure 47 gives similar results with reduced dc offset and low frequency noise.

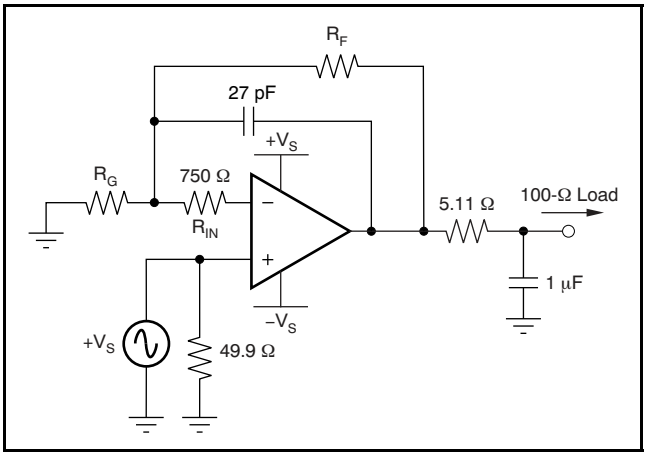

Figure 46. Feedback Technique with Input Resistor for Capacitive Load

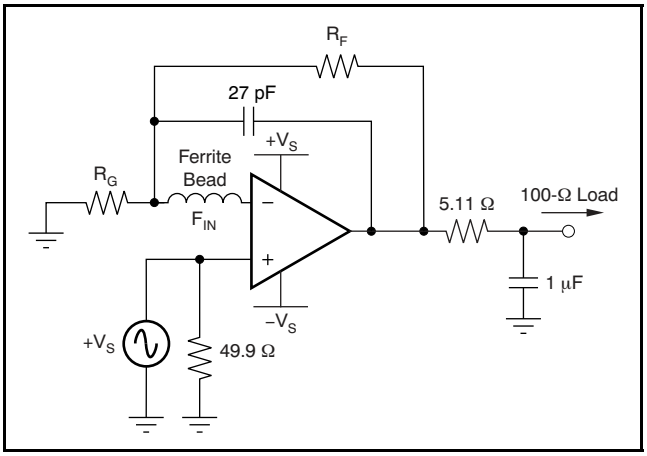

Figure 47. Feedback Technique with Input Ferrite Bead for Capacitive Load

Figure 48 shows a configuration that uses two amplifiers in parallel to double the output drive current to larger capacitive loads. This technique is used when more output current is needed to charge and discharge the load faster as when driving large FET transistors.

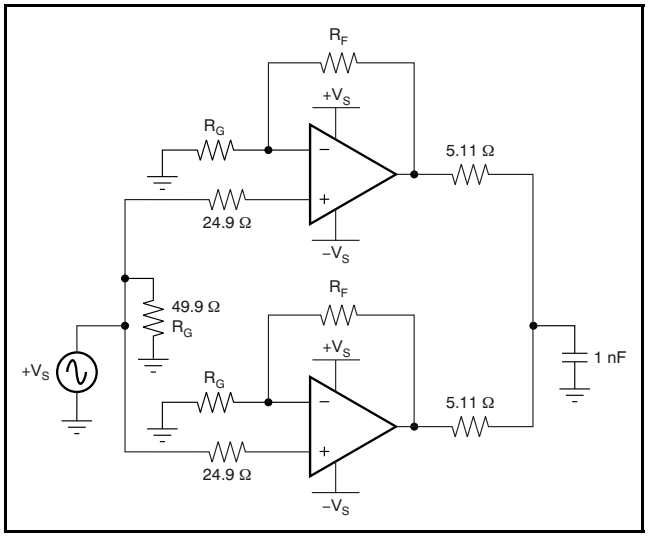

Figure 48. Parallel Amplifiers for Higher Output Drive

Figure 49 shows a push-pull FET driver circuit typical of ultrasound applications with isolation resistors to isolate the gate capacitance from the amplifier.

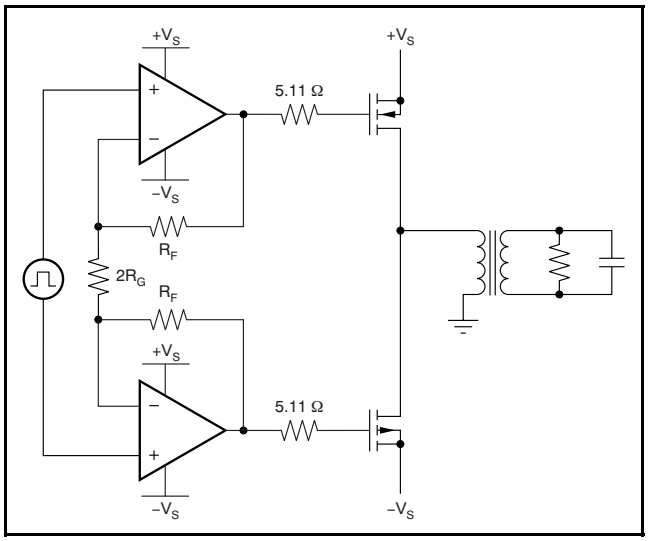

Figure 49. PowerFET Drive Circuit

Saving Power with Shutdown Functionality and Setting Threshold Levels with the Reference Pin

The THS3115 features a shutdown pin (SHUTDOWN) that lowers the quiescent current from 4.9 mA/amp down to 300 µA/amp, ideal for reducing system power.

The shutdown pin of the amplifier defaults to the REF pin voltage in the absence of an applied voltage, putting the amplifier in the normal on mode of operation. To turn off the amplifier in an effort to conserve power, the shutdown pin can be driven towards the positive rail. The threshold voltages for power-on and power-down (or shutdown) are relative to the supply rails and are given in the *Shutdown Characteristics* table. Below the *Enable* threshold voltage, the device is on. Above the *Disable* threshold voltage, the device is off. Behavior between these threshold voltages is not specified.

Note that this shutdown functionality is self-defining: the amplifier consumes less power in shutdown mode. The shutdown mode is not intended to provide a high-impedance output. In other words, the shutdown functionality is not intended to allow use as a 3-state bus driver. When in shutdown mode, the impedance looking back into the output of the amplifier is dominated by the feedback and gain setting resistors, but the output impedance of the device itself varies depending on the voltage applied to the outputs.

As with most current feedback amplifiers, the internal architecture places some limitations on the system when in shutdown mode. Most notably is the fact that the amplifier actually turns *on* if there is a ±0.7 V or greater difference between the two input nodes (IN+ and IN–) of the amplifier. If this difference exceeds ±0.7 V, the output of the amplifier creates an output voltage equal to approximately [(IN+ – IN–) – 0.7V] × Gain. Also, if a voltage is applied to the output while in shutdown mode, the IN– node voltage is equal to $V_{O(applied)} \times R_G/(R_F + R_G)$. For low gain configurations and a large applied voltage at the output, the amplifier may actually turn on because of the behavior described here.

The time delays associated with turning the device on and off are specified as the time it takes for the amplifier to reach either 10% or 90% of the final output voltage. The time delays are in the order of microseconds because the amplifier moves in and out of the linear mode of operation in these transitions.

Power-Down Reference Pin Operation

In addition to the shutdown pin, the THS3115 features a reference pin (REF) which allows the user to control the enable or disable power-down voltage levels applied to the SHUTDOWN pin. In most split-supply applications, the reference pin is connected to ground. In either case, the user needs to be aware of voltage-level thresholds that apply to the shutdown pin. Table 2 shows examples and illustrate the relationship between the reference voltage and the shutdown thresholds. In the table, the threshold levels are derived by the following equations:

SHUTDOWN ≤ REF + 0.8 V for enable

SHUTDOWN ≥ REF + 2V for disable

Where the usable range at the REF pin is:

$$V_{CC-} \le V_{REF} \le (V_{CC+} - 4V)$$

The recommended mode of operation is to tie the REF pin to midrail, therefore setting the enable/disable thresholds to $V_{(midrail)}$ + 0.8 V and $V_{(midrail)}$ = 2 V, respectively.

Table 2. Shutdown Threshold Voltage Levels

SUPPLY VOLTAGE (V)	REFERENCE PIN VOLTAGE (V)	ENABLE LEVEL (V)	DISABLE LEVEL (V)
±15, ±5	0	0.8	2.0
±15	2.0	2.8	4.0
±15	–2.0	–1.2	0
±5	1.0	1.8	3.0
±5	–1.0	–0.2	1.0
+30	15.0	15.8	17
+10	5.0	5.8	7.0

Note that if the REF pin is left unterminated, it floats to the positive rail and falls outside of the recommended operating range given above $V_{CC-} \le V_{REF} \le (V_{CC+} - 4V)$. As a result, it no longer serves as a reliable reference for the SHUTDOWN pin, and the enable/disable thresholds given above no longer apply. If the SHUTDOWN pin is also left unterminated, it floats to the positive rail and the device is disabled. If balanced, split supplies are used ($\pm V_{CC}$) and the REF and SHUTDOWN pins are grounded, the device is enabled.

Printed-Circuit Board Layout Techniques for Optimal Performance

Achieving optimum performance with high-frequency amplifiers such as the THS3115 and THS3112 requires careful attention to board layout parasitic and external component types. Recommendations that optimize performance include:

- Minimize parasitic capacitance to any ac ground for all of the signal I/O pins. Parasitic capacitance on the output and input pins can cause instability. To reduce unwanted capacitance, a window around the signal I/O pins should be opened in all of the ground and power planes around those pins. Otherwise, ground and power planes should be unbroken elsewhere on the board.
- Minimize the distance [0.25 inch, (6,4 mm)] from the power-supply pins to high-frequency 0.1-µF and 100-pF decoupling capacitors. At the device pins, the ground and power plane layout should not be in close proximity to the signal I/O pins. Avoid narrow power and ground traces to minimize inductance between the pins and the decoupling capacitors. The power-supply connections should always be decoupled with these capacitors. Larger (6.8 µF or more) tantalum decoupling capacitors, effective at lower frequencies, should also be used on the main supply pins. These capacitors may be placed somewhat farther from the device and may be shared among several devices in the same area of the printed circuit board (PCB).
- Careful selection and placement of external components preserve the high-frequency performance of the THS3115 and THS3112. Resistors should be a very low reactance type. Surface-mount resistors work best and allow a tighter overall layout. Again, keep the leads and PCB trace length as short as possible. Never use wirebound type resistors in a high-frequency application. Because the output pin and inverting input pins are the most sensitive to parasitic capacitance, always position the feedback and series output resistors, if any, as close as possible to the inverting input pins and output pins. Other network components, such as input termination resistors, should be placed close to the gain-setting resistors. Even with a low parasitic capacitance that shunts the external resistors, excessively high resistor values can create significant time constants that can degrade performance. Good axial metal-film or surface-mount resistors have approximately 0.2 pF in shunt with the resistor. For resistor values greater than 2.0 kΩ, this parasitic capacitance can add a pole and/or a zero that can affect circuit operation. Keep resistor values as low as possible, consistent with load driving considerations.

- Connections to other wideband devices on the board may be made with short direct traces or through onboard transmission lines. For short connections, consider the trace and the input to the next device as a lumped capacitive load. Relatively wide traces [0.05 inch (1,3 mm) to 0.1 inch (2,54 mm)] should be used, preferably with ground and power planes opened up around them. Estimate the total capacitive load and determine if isolation resistors on the outputs are necessary. Low parasitic capacitive loads (less than 4 pF) may not need an R_S because the THS3115 and THS3112 are nominally compensated to operate with a 2-pF parasitic load. Higher parasitic capacitive loads without an R_S are allowed as the signal gain increases (thus increasing the unloaded phase margin). If a long trace is required, and the 6-dB signal loss intrinsic to a doubly-terminated transmission line is acceptable, implement a matched-impedance transmission line using microstrip or stripline techniques (consult an ECL design handbook for microstrip and stripline layout techniques). A 50-Ω environment is not necessary onboard, and in fact, a higher impedance environment improves distortion as shown in the distortion versus load plots. With a characteristic board trace impedance based on board material and trace dimensions, a matching series resistor into the trace from the output of the THS3115/THS3112 is used as well as a terminating shunt resistor at the input of the destination device. Remember also that the terminating impedance is the parallel combination of the shunt resistor and the input impedance of the destination device: this total effective impedance should be set to match the trace impedance. If the 6-dB attenuation of a doubly-terminated transmission line is unacceptable, a long trace can be series-terminated at the source end only. Treat the trace as a capacitive load in this case. This configuration does not preserve signal integrity as well as a doubly-terminated line. If the input impedance of the destination device is low, there is some signal attenuation as a result of the voltage divider formed by the series output into the terminating impedance.
- Socketing a high-speed device such as the THS3115 and THS3112 is not recommended. The additional lead length and pin-to-pin capacitance introduced by the socket can create an extremely troublesome parasitic network which can make it almost impossible to achieve a smooth, stable frequency response. Best results are obtained by soldering the THS3115/THS3112 amplifiers directly onto the board.

PowerPAD™ Design Considerations

The THS3115 and THS3112 are available in a thermally-enhanced PowerPAD family of packages. These packages are constructed using a downset leadframe upon which the die is mounted [see Figure 50(a) and Figure 50(b)]. This arrangement results in the lead frame being exposed as a thermal pad on the underside of the package [see Figure 50(c)]. Because this thermal pad has direct thermal contact with the die, excellent thermal performance can be achieved by providing a good thermal path away from the thermal pad. Note that devices such as the THS311x have no electrical connection between the PowerPAD and the die.

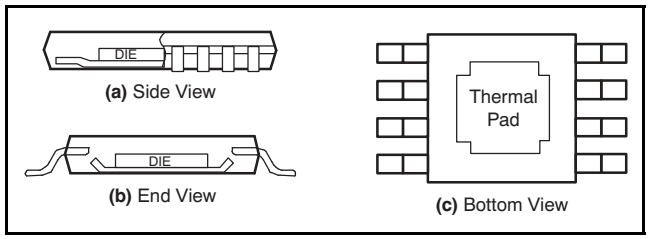

Figure 50. Views of Thermally-Enhanced Package

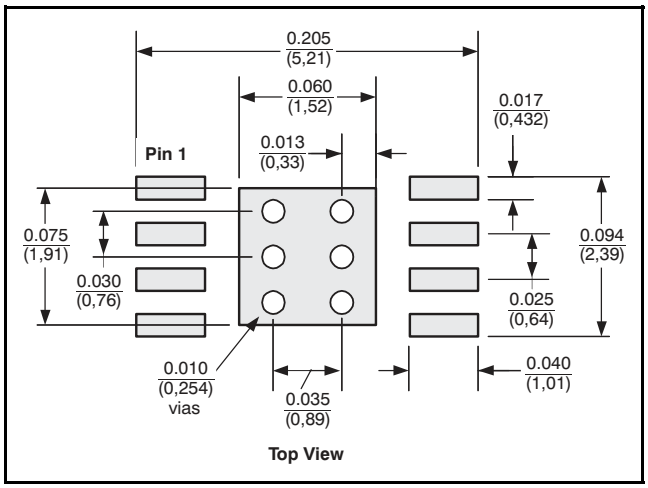
The PowerPAD package allows for both assembly and thermal management in one manufacturing operation. During the surface-mount solder operation (when the leads are being soldered), the thermal pad can also be soldered to a copper area underneath the package. Through the use of thermal paths within this copper area, heat can be conducted away from the package into either a ground plane or other heat dissipating device.

The PowerPAD package represents a breakthrough in combining the small area and ease of assembly of surface mount with the, heretofore, awkward mechanical methods of heatsinking.

PowerPAD™ Layout Considerations



Dimensions are in inches (millimeters).

Figure 51. DGN PowerPAD PCB Etch and Via Pattern

Although there are many ways to properly heatsink the PowerPAD package, the following steps illustrate the recommended approach.

1. PCB with a top side etch pattern as shown in Figure 51.
2. Place five holes in the area of the thermal pad. These holes should be 0.01 inch (0,254 mm) in diameter. Keep them small so that solder wicking through the holes is not a problem during reflow.
3. Additional vias may be placed anywhere along the thermal plane outside of the thermal pad area. These vias help dissipate the heat generated by the THS3115/THS3112 IC. These additional vias may be larger than the 0.01-inch (0,254-mm) diameter vias directly under the thermal pad. They can be larger because they are not in the thermal pad area to be soldered so that wicking is not a problem.
4. Connect all holes to the internal ground plane. Note that the PowerPAD is electrically isolated from the silicon and all leads. Connecting the PowerPAD to any potential voltage, such as V_{S-}, is acceptable as there is no electrical connection to the silicon.
5. When connecting these holes to the ground plane, do not use the typical web or spoke via connection methodology. Web connections have a high thermal resistance connection that is useful for slowing the heat transfer during soldering operations. This resistance makes the soldering of vias that have plane connections easier. In this application; however, low thermal resistance is desired for the most efficient heat transfer. Therefore, the holes under the THS3115/THS3112 PowerPAD package should make the connection to the internal ground plane with a complete connection around the entire circumference of the plated-through hole.
6. The top-side solder mask should leave the terminals of the package and the thermal pad area with its five holes exposed. The bottom-side solder mask should cover the five holes of the thermal pad area. This configuration prevents solder from being pulled away from the thermal pad area during the reflow process.
7. Apply solder paste to the exposed thermal pad area and all of the IC terminals.
8. With these preparatory steps in place, the IC is simply placed in position and run through the solder reflow operation as any standard surface-mount component. This procedure results in a part that is properly installed.

Power Dissipation and Thermal Considerations

The THS3115 and THS3112 incorporate automatic thermal shutoff protection. This protection circuitry shuts down the amplifier if the junction temperature exceeds approximately +160°C. When the junction temperature reduces to approximately +140°C, the amplifier turns on again. However, for maximum performance and reliability, the designer must take care to ensure that the design does not exceed a junction temperature of +125°C. Between +125°C and +150°C, damage does not occur, but the performance of the amplifier begins to degrade and long-term reliability suffers. The thermal characteristics of the device are dictated by the package and the PCB. Maximum power dissipation for a given package can be calculated using the following formula.

$$P_{DMax} = \frac{T_{max} - T_A}{\theta_{JA}}$$

where:

- P_{DMax} is the maximum power dissipation in the amplifier (W)
- T_{max} is the absolute maximum junction temperature (°C)
- T_A is the ambient temperature (°C)

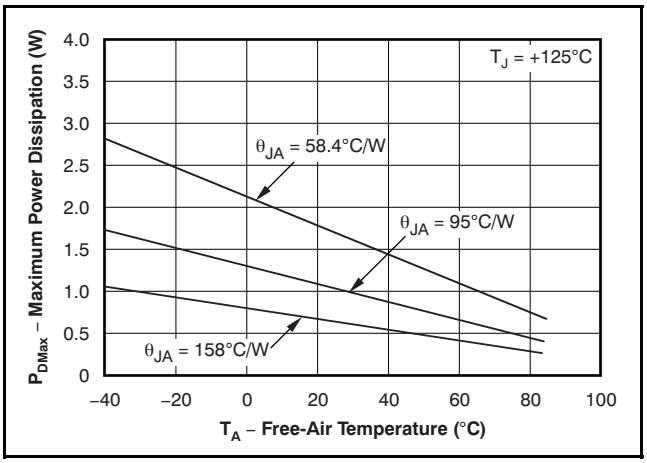
$$\theta_{JA} = \theta_{JC} + \theta_{CA}$$

where:

- θ_{JC} is the thermal coefficient from the silicon junctions to the case (°C/W)
- θ_{CA} is the thermal coefficient from the case to ambient air (°C/W)

For systems where heat dissipation is more critical, the THS3115 and THS3112 are also available in an 8-pin MSOP with PowerPAD package that offers even better thermal performance. The thermal coefficient for the PowerPAD packages are substantially improved over the traditional SOIC. Maximum power dissipation levels are depicted in Figure 52 for the available packages. The data for the PowerPAD packages assume a board layout that follows the PowerPAD layout guidelines discussed above and detailed in the PowerPAD application note (literature number SLMA002). Figure 52 also illustrates the effect of not soldering the PowerPAD to a PCB. The thermal impedance increases substantially, which may cause serious heat and performance issues. Always solder the PowerPAD to the PCB for optimum performance.

When determining whether or not the device satisfies the maximum power dissipation requirement, it is important to not only consider quiescent power dissipation, but also dynamic power dissipation. Often times, this type of dissipation is difficult to quantify because the signal pattern is inconsistent, but an estimate of the RMS power dissipation can provide visibility into a possible problem.



Results shown are with no air flow and PCB size of 3 in × 3 in (76,2 mm × 76,2 mm).

- θ_{JA} = 58.4°C/W for 8-pin MSOP with PowerPAD (DGN package)
- θ_{JA} = 95°C/W for 8-pin SOIC High-K test PCB (D package)
- θ_{JA} = 158°C/W for 8-pin MSOP with PowerPAD without solder

Figure 52. Maximum Power Dissipation vs Ambient Temperature

REVISION HISTORY

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

Changes from Revision B (October, 2009) to Revision C **Page**

- Corrected pin designations for TSSOP pinout drawing 1
- Deleted *Shutdown pin input levels* parameters from Recommended Operating Conditions table 3
- Added V_{REF} parameter to Shutdown Characteristics table 5
- Added V_{SHDN} parameter to Shutdown Characteristics table 5
- Changed reference to GND pin to "REF" in *Shutdown quiescent current* parameter test conditions in Shutdown Characteristics table 5
- Added REF = 0 V to test conditions for $I_{IL(SHDN)}$ parameter in Shutdown Characteristics table 5
- Added REF = 0 V to test conditions for $I_{IH(SHDN)}$ parameter in Shutdown Characteristics table 5
- Revised *Saving Power with Shutdown Functionality and Setting Threshold Levels with the Reference Pin* section 14
- Updated *Power-Down Reference Pin Operation* section; changed references to $V_{S–}$, V_{S+} to $V_{CC–}$, V_{CC+} 15

Changes from Revision A (January, 2009) to Revision B **Page**

- Updated document format to conform to current standards 1
- Deleted lead temperature specification from *Absolute Maximum Ratings* table 2
- Added *Application Information* section 11

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".
RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.
Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
