

# Si1133 Data Sheet

# UV Index/Ambient Light Sensor IC with I<sup>2</sup>C Interface

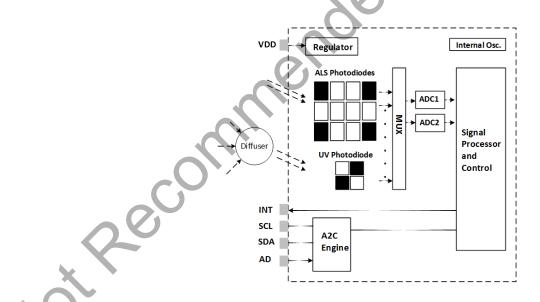

The Si1133 is a UV Index Sensor and Ambient Light Sensor with  $I^2C$  digital interface and programmable-event interrupt output. This sensor IC includes dual 23-bit analog-to-digital converters, integrated high-sensitivity array of UV, visible and infrared photodiodes, and digital signal processor. The Si1133 is provided in a 10-lead 2x2 mm DFN package and capable of operation from 1.62 to 3.6 V over the -40 to +85 °C temperature range.

### **Applications**

- Wearables
- Handsets
- · Display backlighting control
- · Consumer electronics

#### KEY FEATURES

- High accuracy UV index sensor (0 to > 20 uV)
  - · Matches erythermal curve
- Ambient light sensor
  - <100 mlx resolution possible, allowing operation under dark glass</li>
  - Up to 128 klx dynamic range possible across two ADC range settings
- Industry's lowest power consumption
- 1.62 to 3.6 V supply voltage
- <500 nA standby current</li>
- · Internal and external wake support
- Built-in voltage supply monitor and power-on reset controller

#### 1. Feature List

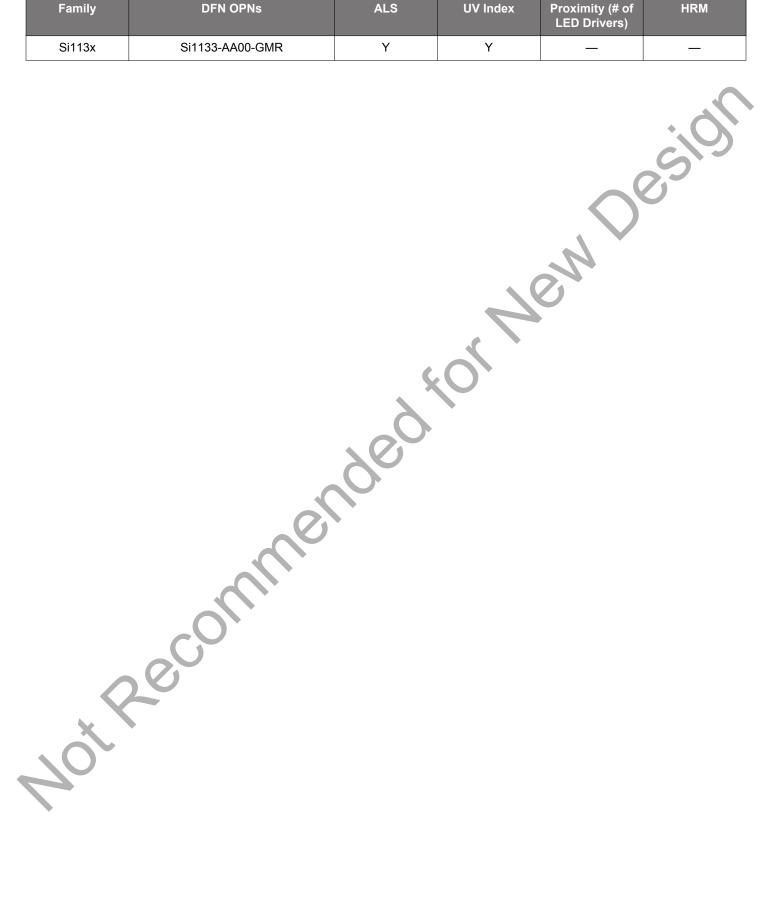

- · High accuracy UV index sensor
  - · Matches erythermal curve
- · Ambient light sensor
  - <100 mlx resolution possible, allowing operation under dark glass<100 mlx resolution possible, allowing operation under dark glass
  - Up to 128 klx dynamic range possible across two ADC range settings
- · Industry's lowest power consumption
  - 1.62 to 3.6 V supply voltage
  - · <500 nA standby current

  - ot Recommended for New

- · Trimmable internal oscillator with typical 1% accuracy
- · I2C Serial communications
  - · Up to 3.4 Mbps data rate
  - · Slave mode hardware address decoding
- · Small package options
  - 10-lead 2 x 2 x 0.65 mm QFN
- Temperature Range: -40 to +85 °C

#### 3. Functional Description

The Si1133 is a UV and Ambient Light sensor whose operational state is controlled through registers accessible through the I<sup>2</sup>C interface. The host can command the Si1133 to initiate on-demand UV or Ambient Light measurement. The host can also place the Si1133 in an autonomous operational state where it performs measurements at set intervals and interrupts the host either after each measurement is completed or whenever a set threshold has been crossed. This results in an overall system power saving allowing the host controller to operate longer in its sleep state instead of polling the Si1133.

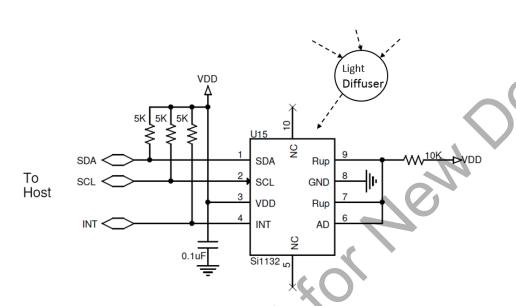

Figure 3.1. Si1133 Basic Application

### 3.1 Ambient Light Sensing

The Si1133 has photodiodes capable of measuring visible and infrared light. However, the visible photodiode is also influenced by infrared light. The measurement of illuminance requires the same spectral response as the human eye. If an accurate lux measurement is desired, the extra IR response of the visible-light photodiode must be compensated. Therefore, to allow the host to make corrections to the infrared light's influence, the Si1133 reports the infrared light measurement on a separate channel. The separate visible and IR photodiodes lend themselves to a variety of algorithmic solutions. The host can then take these two measurements and run an algorithm to derive an equivalent lux level as perceived by a human eye. Having the IR correction algorithm running in the host allows for the most flexibility in adjusting for system-dependent variables. For example, if the glass used in the system blocks visible light more than infrared light, the IR correction needs to be adjusted.

If the host is not making any infrared corrections, the infrared measurement can be turned off in the CHAN LIST parameter.

By default, the measurement parameters are optimized for indoor ambient light levels, where it is possible to detect low light levels. For operation under direct sunlight, the ADC can be programmed to operate in a high signal operation so that it is possible to measure direct sunlight without overflowing.

For low-light applications, it is possible to increase the ADC integration time. Normally, the integration time is 24.4 µs. By increasing this integration time, the ADC can detect light levels as low as 100 mlx. The ADC integration time for the Visible Light Ambient measurement can be programmed independently of the ADC integration time of the Infrared Light Ambient measurement. The independent ADC parameters allow operation under glass covers having a higher transmittance to Infrared Light than Visible Light.

When operating in the lower signal range, or when the integration time is increased, it is possible to saturate the ADC when the ambient light suddenly increases. Any overflow condition will have the corresponding data registers report a value of 0xFFddFF for 16-bit mode and 0x7FFFFF for 24-bit mode. The host can adjust the ADC sensitivity to avoid an overflow condition. If the light levels return to a range within the capabilities of the ADC, the corresponding data registers begin to operate normally.

The Si1133 can initiate ALS measurements either when explicitly commanded by the host or periodically through an autonomous process. Refer to Section 4. Operational Modes for additional details.

Two ADCs can be used for simultaneous readings of the visible or UV photodiode and black dark current reference photodiode. When subtracted, these differential measurements remove dark current, reducing noise that enables lower light sensitivity.

#### 3.2 Ultraviolet (UV) Index Sensing

The UV Index is a number linearly related to the intensity of sunlight reaching the earth and is weighted according to the CIE erythema Action Spectrum as shown in Figure 4. This weighting is a standardized measure of human skin's response to different wavelengths of sunlight from UVB to UVA. The UV Index has been standardized by the World Health Organization as shown in the figure below.

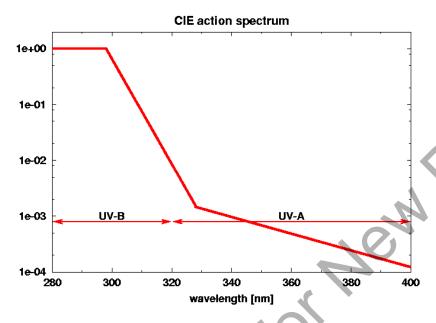

Figure 3.2. CIE Erythemal Action Spectrum

Figure 3.3. UV Index Scale

Isolated UV photodiodes that closely match the erythema curve for accurate UV Index measurements. Matching dark current reference photodiodes are also provided to cancel UV photodiode noise. The typical calibrated UV Index sensor response vs. calculated ideal UV Index is shown below for several cloudy and sunny days and at various angles of the sun/time of day.

Given the possible variation of the overlay materials above the Si1133, it is generally recommended that outgoing factory calibration be performed at the outgoing test to decrease system-to-system variation.

The performance of the Si1133 is best when under a Teflon diffuser while diffuser is within +/- 30 degrees of the sensor view angle. See the plot below.

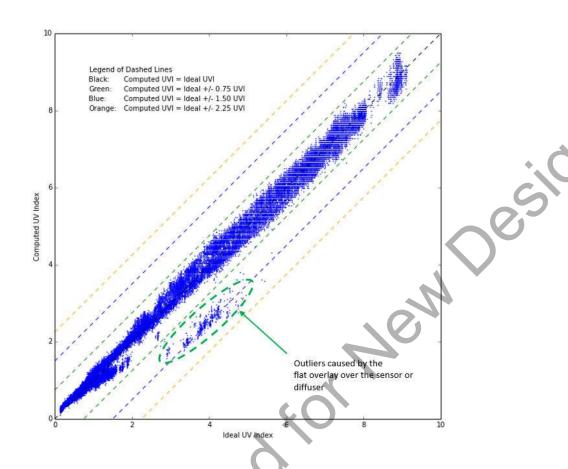

Figure 3.4. Typical UV Index Scatter Plot (+/- 30 ° Angular View of a Teflon Diffuser)

### The test setup is as follows:

Overlay	Corning Gorilla © Glass (0.7 mm thick)
Diffuser	0.8 mm dia. diffuser, 0.25 mm above QFN package, under glass
ADC Gain	9
Decimation Filter Setting	3
Samples Averaged / Reading	1
Formula	UV index = 0.0187(0.00391 Input <sup>2</sup> + Input)

#### 3.3 Power Consumption

The Si1133 alternates between three power consumption states: Active, Suspend, and Sleep. (See the diagram below for an illustratation of each of these states.) The total power consumed by the part depends heavily on the measurement rate, measurement mode, and measurement gain for the various channels enabled. The power levels for the three modes, as well as the Active Power time per reading, are provided in this document. The Suspend time (where the A/D and PD are operating) has two parts. One is determined by the user setup and can be determined by the DECIM\_RATE and HW\_GAIN setup information, while the other (A/D Startup time) is determined by tadstart, shown in Table 8.2 Performance Characteristics<sup>1</sup> on page 35.

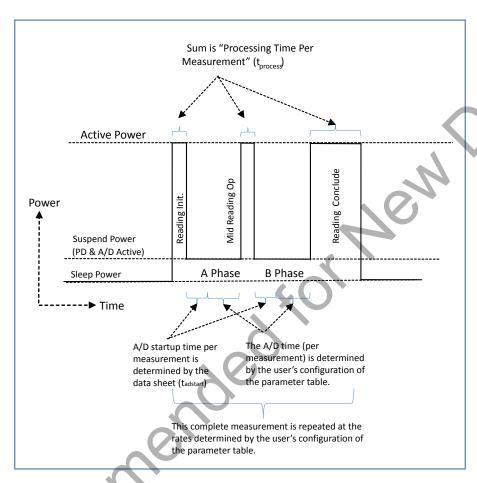

Figure 3.5. Power Consumption States During a Reading

Every A/D conversion has three periods:

155 µs at 4.5 mA (setup time by internal controller)

48.8 μs at 525 μA (setup time by A/D)

48.8 µs \* (2 \*\* gain) at 525 µA (Actual A/D time that will vary with integration time)

#### 3.4 Host Interface

The host interface to the Si1133 consists of three pins:

- SCL
- SDA
- INT

SCL and SDA are standard open-drain pins as required for  $I^2C$  operation. The Si1133 asserts the INT pin to interrupt the host processor. The INT pin is an open-drain output. A pull-up resistor is needed for proper operation. As an open-drain output, it can be shared with other open-drain interrupt sources in the system.

For proper operation, the Si1133 is expected to fully complete its Initialization Mode prior to any activity on the I<sup>2</sup>C.

The INT, SCL, and SDA pins are designed so that it is possible for the Si1133 to enter the Off Mode by software command without interfering with normal operation of other I<sup>2</sup>C devices on the bus.

The I<sup>2</sup>C interface allows access to the Si1133 internal registers.

An I<sup>2</sup>C write access always begins with a start (or restart) condition. The first byte after the start condition is the I2C address and a read-write bit. The second byte specifies the starting address of the Si1133 internal register. Subsequent bytes are written to the Si1133 internal register sequentially until a stop condition is encountered. An I<sup>2</sup>C write access with only two bytes is typically used to set up the Si1133 internal address in preparation for an I<sup>2</sup>C read.

The  $I^2C$  read access, like the  $I^2C$  write access, begins with a start or restart condition. In an  $I^2C$  read, the  $I^2C$  master then continues to clock SCK to allow the Si1133 to drive the  $I^2C$  with the internal register contents. The Si1133 also supports burst reads and burst writes. The burst read is useful in collecting contiguous, sequential registers. The Si1133 register map was designed to optimize for burst reads for interrupt handlers, and the burst writes are designed to facilitate rapid programming of commonly used fields, such as thresholds registers.

The internal register address is a six-bit (bit 5 to bit 0) plus an Auto increment Disable (on bit 6). The Auto increment Disable is turned off by default. Disabling the auto incrementing feature allows the host to poll any single internal register repeatedly without having to keep updating the Si1133 internal address every time the register is read.

It is recommended that the host should read performance measurements (in the I<sup>2</sup>C Register Map) when the Si1133 asserts INT. Although the host can read any of the Si1133's I<sup>2</sup>C registers at any time, care must be taken when reading 2-byte measurements outside the context of an interrupt handler. The host could be reading part of the 2-byte measurement when the internal sequencer is updating that same measurement coincidentally. When this happens, the host could be reading a hybrid 2-byte quantity whose high byte and low byte are parts of different samples. If the host must read these 2-byte registers outside the context of an interrupt handler, the host should "double-check" a measurement if the measurement deviates significantly from a previous reading.

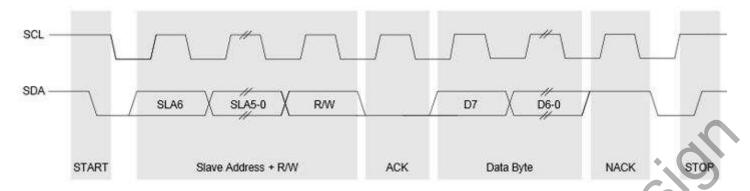

Figure 3.6. I<sup>2</sup>C Bit Timing Diagram

Figure 3.8. Host Interface Single Read

Figure 3.9. Host Interface Burst Write

Figure 3.10. Host Interface Burst Read

Figure 3.11. Si1133 REG ADDRESS Format

The following notes apply for the figures above:

- 1. Gray boxes are driven by the host to the Si1133.
- 2. White boxes are driven by the Si1133.
- 3. A = ACK or "acknowledge".
- 4. N = NACK or "no acknowledge".
- 5. S = START condition.
- 6. Sr = repeat START condition.
- 7. P = STOP condition.
- 8. AI = Disable Auto Increment when set.

### 4. Operational Modes

The Si1133 can be in one of many operational modes at any time. It is important to consider the operation mode, since the mode has an impact on the overall power consumption of the Si1133. The various modes are:

- · Off Mode
- · Initialization Mode
- · Standby Mode
- · Forced Conversion Mode
- · Autonomous Mode

#### 4.1 Off Mode

The Si1133 is in the Off Mode when  $V_{DD}$  is either not connected to a power supply or if the  $V_{DD}$  voltage is below the stated VDD\_OFF voltage described in the electrical specifications. As long as the parameters stated in are not violated, no current will flow through the Si1133. In the Off Mode, the Si1133 SCL and SDA pins do not interfere with other  $I^2C$  devices on the bus. Keeping  $V_{DD}$  less than VDD\_OFF is not intended as a method of achieving lowest system current draw. The reason is that the ESD protection devices on the SCL, SDA, and INT pins also draw from a current path through  $V_{DD}$ . If  $V_{DD}$  is grounded, for example, then current flows from system power to system ground through the SCL, SDA, and INT pull-up resistors and the ESD protection devices. Allowing  $V_{DD}$  to be less than VDD OFF is intended to serve as a hardware method of resetting the Si1133 without a dedicated reset pin.

The Si1133 can also re-enter the Off Mode upon receipt of a software reset sequence. Upon entering Off Mode, the Si1133 proceeds directly from the Off Mode to the Initialization Mode.

#### 4.2 Initialization Mode

When power is applied to  $V_{DD}$  and is greater than the minimum  $V_{DD}$  Supply Voltage stated in the electrical specification table, the Si1133 enters its Initialization Mode. In the Initialization Mode, the Si1133 performs its initial startup sequence. Since the  $I^2C$  may not yet be active, it is recommended that no  $I^2C$  activity occur during this brief Initialization Mode period. The "Start-up time" specification in the electrical specification table is the minimum recommended time the host needs to wait before sending any  $I^2C$  accesses following a power-up sequence. After Initialization Mode has completed, the Si1133 enters Standby Mode. During the Initialization mode, the  $I^2C$  address selection is made according to whether LED2 is pulled up or down.

#### 4.3 Standby Mode

The Si1133 spends most of its time in Standby Mode. After the Si1133 completes the Initialization Mode sequence, it enters Standby Mode. While in Standby Mode, the Si1133 does not perform any Ambient Light or UV measurements. However, the I<sup>2</sup>C interface is active and ready to accept reads and writes to the Si1133 registers. The internal Digital Sequence Controller is in its sleep state and does not draw much power. In addition, the INT output retains its state until it is cleared by the host.

 $I^2C$  accesses do not necessarily cause the Si1133 to exit the Standby Mode. For example, reading Si1133 registers is accomplished without needing the Digital Sequence Controller to wake from its sleep state.

### 4.4 Forced Conversion Mode

The Si1133 can operate in Forced Conversion Mode under the specific command of the host processor. The Forced Conversion Mode is entered when the FORCE command is sent. Upon completion of the conversion, the Si1133 can generate an interrupt to the host if the corresponding interrupt is enabled. It is possible to initiate both a UV and ALS measurement.

### 4.5 Automated Operation Mode

The Si1133 can be placed in the Autonomous Operation Mode where measurements are performed automatically without requiring an explicit host command for every measurement. The START command is used to place the Si1133 in the Autonomous Operation Mode.

The Si1133 updates the I<sup>2</sup>C registers for UV and ALS automatically. The host can also choose to be notified when these new measurements are available by enabling interrupts. The conversion frequency for autonomous operation is set up by the host prior to the START command.

The Si1133 can also interrupt the host when the UV or ALS measurement reach a pre-set threshold. To assist in the handling of interrupts the registers are arranged so that the interrupt handler can perform an I<sup>2</sup>C burst read operation to read the necessary registers, beginning with the interrupt status register, and cycle through the various output registers.

#### 5. User to Sensor Communication

### 5.1 Basic I<sup>2</sup>C Operation

 $I^2C$  operation is dependent on serial  $I^2C$  reads and writes to an addressable bank of memory referred to as  $I^2C$  space. The diagram below outlines the registers used, some functionality and the direction of data flow. The  $I^2C$  address is initially fixed but can be programmed to a new value. This new value is volatile and reverts to the old value on hardware or software reset. Only 7-bit  $I^2C$  addressing is supported; 10-bit  $I^2C$  addressing is not supported. The Si1133 responds to the  $I^2C$  address of 0x55 or to an alternate address of 0x52.

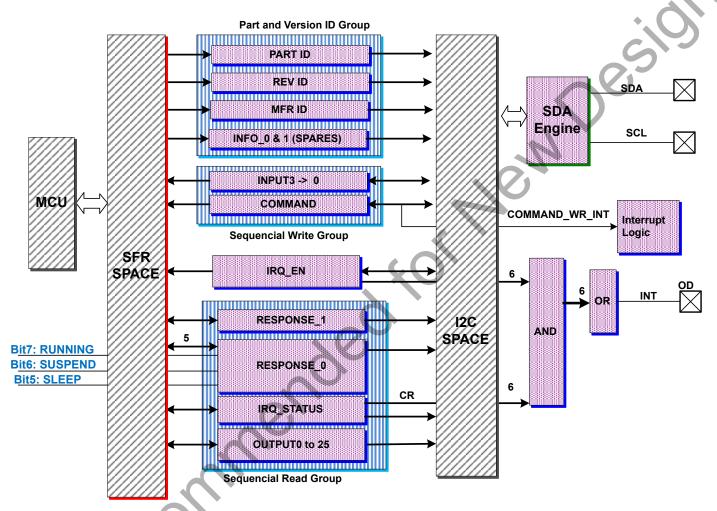

Figure 5.1. I<sup>2</sup>C Interface Block Diagram

#### 5.2 Relationship Between I<sup>2</sup>C Registers and Parameter Table

Note that most of the Si1133 configuration is accomplished through 'Parameters'. The Si1133 has an internal MCU with SRAM. The Parameters are stored in the Si1133 Internal MCU SRAM. The I<sup>2</sup>C Registers can be viewed as mailbox registers that form an interface between the host and the internal MCU. The figure below shows the relationship between some of the key interface registers to the internal Parameters managed by the internal MCU.

- The I<sup>2</sup>C registers are directly accessible by the host.
- · The parameter table is:
  - · Accessible indirectly via the command register (and others).
  - Used during setup to fix the operating modes of the Si1133.
  - 0x2C bytes long and is read and written indirectly, one bye at a time, via the command register.

The data stored in the parameter table is volatile and is lost when the part is powered down or software reset command is sent to the part via the I<sup>2</sup>C part.

#### 5.3 I<sup>2</sup>C Command Register Operation

Writing the codes shown below in the command summary table signals the sensor to undertake one of several complex operations.

These operations take time and all commands should be followed by a read of the RESPONSE0 register to confirm the operation is complete by examining the counter and to check for an error in the error bit. The error bit is set in the RESPONSE0 register's command counter if there is an error in the previous command (e.g., attempt to write to an illegal address beyond the parameter table, or a channel and /or burst configuration that exceeds the size of the output field (26 bytes)). If there is no such error, then the counter portion of the command counter will be incremented.

The RESPONSE\_0 register should be read after every command to determine completion and to check for an error. If an error is found, which should not happen except for a host SW bug, the host should clear the error with a RESET command or a RESET\_CMD\_CTR command.

One operating option is to do a RESET\_CMD\_CTR command before every command.

Two of the commands imply another I<sup>2</sup>C register contains an argument.

- STORE\_NEW\_I2C ADDR command implies a new address has been loaded in the parameter table location I2CID PARAMETER.
- PARAM\_SET command implies a byte has been stuffed into INPUT0 register.
- The three CHAN\_LIST commands imply the CHAN\_LIST location in the parameter table has been configured. A valid CHAN\_LIST implies other configuration areas in the parameter table are correctly setup as well.

Two of the commands result in another I<sup>2</sup>C register containing return arguments (aside from incrementing RESPONSE0).

- PARAM SET results in the write data being copied in to I2C RESPONSE1 register.
- · PARAM QUERY results in read data in the I2C RESPONSE1 register.

Table 5.1. Command Summary

Command Register Commands	Code	Input to Sensor	Output of Sensor
RESET_CMD_CTR	0x00		
Resets RESPONSE0 CMMND_CTR field to 0.			
RESET_SW	0x01		
Forces a Reset, Resets RESPONSE0 CMMND_CTR field to 0xXXX01111.			(0)
FORCE	0x11		
Initiates a set of measurements specified in CHAN_LIST parameter. A FORCE command will only execute the measurements which do not have a meas counter index configured in MEAS-CONFIGx.			000
PAUSE	0x12		
Pauses autonomous measurements specified in CHAN_LIST.		70	
START	0x13		
Starts autonomous measurements specified in CHAN_LIST. A START autonomous command will only start the measurements which has a counter index selected in MEASCONFIGx.	2 %	0	
PARAM_QUERY	0b01xxxxxx		RESPONSE1 = result
Reads Parameter xxxxxx and store results in RE-SPONSE1.xxxxxx is a 6 bit Address Field (64 bytes).	96		
PARAM_SET	0b10xxxxxx	INPUT0	RESPONSE1 = INPUT0
Writes INPUT0 to the Parameter xxxxxxxxxxxx is a 6 bit Address Field (64 bytes).			

#### Notes:

- 1. The successful completion of all commands except RESET\_CMD\_CTR and RESET\_SW causes an increment of the CMD\_CTR field of the RESPONSE0 register (bits [3:0].
- 2. Resets RESPONSE0 CMMND\_CTR field to 0.
- 3. Forces a Reset, Resets RESPONSE0 CMMND\_CTR field to 0xXXX01111.
- 4. Uses CHAN\_LIST in Parameter Space.
- 5. "xxxxxx" is a 6-bit Address Field (64 bytes).

#### 5.3.1 Accessing the Parameter Table (PARAM\_QUERY & PARAM\_SET Commands)

The parameter table is written to by writing the INPUT\_0 I2C register and the PARAM\_SET command byte to the Command I<sup>2</sup>C register. The format of the PARAM\_SET word is such that the 6 LSBits contain the location of the target byte in the parameter table.

**Example:** To transfer 0xA5 to parameter table location 0b010101.

Read RESPONSE0 (address 0x11) and store the CMMND CTR field.

Write 0xA5 to INPUT0 (address 0x0A).

Write 0b10010101 to COMMAND (address 0x0B).

Read RESPONSE0 (address 0x11) and check if the CMMND CTR field incremented.

If there is no increment or error, repeat the "read the RESPONSE0" step until the CMMND\_CTR has incremented. If there is an error send a RESET or a RESET CMD CTR command.

The two write commands (to INPUT0 and COMMAND) can be in the same I<sup>2</sup>C transaction.

**Example:** To read data from the parameter table location 0b010101.

Read the RESPONSE0 (address 0x11) and store the CMMND CTR field.

Write 0b01010101 to the COMMAND (address 0x0B).

Read RESPONSE0 (address 0x11) and check if the CMMND CTR field incremented.

If there is no increment or error, repeat the "read RESPONSE0" step until the CMMND CTR has incremented.

Read RESPONSE1 (address 0x10) this gives the read result. If there is an error send RESET or a RESET CMD CTR com-

mand.

The last two read commands (from RESPONSE0 and RESPONSE1) should not be in the same I<sup>2</sup>C transaction.

#### 5.3.2 Sensor Operation Initiation Commands

The FORCE, PAUSE, and START commands make use of the information in CHAN\_LIST. Configure CHAN\_LIST prior to using any of these commands.

#### 5.3.3 RESET\_CMD\_CTR Command

Resets RESPONSE0 CMMND CTR field and does nothing else.

#### 5.3.4 RESET Command

Resets the sensor and puts it into the same state as when powering up. The parameter table and all I<sup>2</sup>C registers are reset to their default values.

### 5.4 I<sup>2</sup>C Register Summary

The content of the three MSBits of Response0 after reset will depend on the running state (see the Response0 write up).

Table 5.2. I2C Registers

Register Name	I2C Address	Direction WRT Host	Function	Value after Reset (Hard or Soft)	Direction WRT Sensor
PART_ID	0x00	IN	Returns DEVID (0x33 for the Si1133).	PART_ID	OUT
HW_ID	0x01	IN	Returns Hardware ID.	HW_ID	OUT

		IF CMD_ERR = 1	Code	Meaning					
			0x10	Invalid command.					
			0x11	Parameter access to an invalid location.					
•			0x12	Saturation of the ADC or overflow of accumulation.					
			0x13	Output buffer overflow—this can happen when Burst mode is enabled and configured for greater than 26 bytes of output.					

The RESPONSE0 register will show "RUNNING" immediately after reset and then "SLEEP" after initialization is complete.

### 5.4.11 IRQ\_STATUS

### I2C Address = 0x12;

Bit	7	6	5	4	3	2	1	0
Name	_		IRQ5	IRQ4	IRQ3	IRQ2	IRQ1	IRQ0
Туре	RSVD		CR	CR	CR	CR	CR	CR
Reset			0	0	0	0	0	0

Bit	Name	Function
7:6	UNUSED	Unused. Read = 00b; Write = Don't Care.
5	IRQ5	Enables an IRQ for channel 5 result being ready.
4	IRQ4	Enables an IRQ for channel 4 result being ready.
3	IRQ3	Enables an IRQ for channel 3 result being ready.
2	IRQ2	Enables an IRQ for channel 2 result being ready.
1	IRQ1	Enables an IRQ for channel 1 result being ready
0	IRQ0	Enables an IRQ for channel 0 result being ready.

### 5.4.12 HOSTOUTx

This section covers the twenty-six I2C Host Output Registers. These registers are the output of the sensor and input to the host.

Name	I2C Address
HOSTOUT0	0x13
to	to
HOSTOUT25	0x2C

Bit	7	6	5	4	3	2	1	0
Name	HOSTOUTX							
Туре	R							
Reset	0	0	0	0	0	0	0	0

Bit	Name	Function
7:0	HOSTOUTX	These registers are the output of the MCU and input to the host. The results of the CHAN_LIST enabled "active channel" readings are located sequentially in this table. Each channel may use 2 or 3 bytes depending on the setup.
\o`\		The validity of the various channel outputs located in this table is determined by other factors. Data is valid when an IRQ status says that it is and remains valid until another reading happens. This is why it is imperative to service the interrupt before the next measurement cycle begins (Autonomous Mode), unless forced mode is used.

### 6. Measurement: Principle of Operation

Operation is based on the concept of channels. Channels are essentially tasks that have been setup by the user.

To setup these channels, the channel specific areas of the parameter table need to be loaded with the correct information as well as the global area of this table.

The channels' specific areas are described below, including:

- · ADC gain
- · The photodiode selected
- · The counter selected to time
- · How often to make a measurement
- . The format of the output (16 vs. 24 bits)
- · And other areas

The global area includes global information that affect all tasks, such as:

- · The list of channels that are enabled.
- The setup of the two counters that can be used by the channels.
- The three light thresholds that can be selected from by the channels.

The list of channels, CHAN\_LIST, in the global area determines what operations are run and how the results are packed in the output fields.

The packing of the result data in the output fields is totally determined by the enabled channels as they are packed sequentially from the lowest enabled channel to the highest in the output field (I2C space- HOSTOUT0 to HOSTOUT25). The amount of space used by each channel is determined by the 16 vs. 24 bit selection made in the channel setup.

Although space in the output buffer is reserved by the CHAN\_LIST, the data validity is determined by the IRQ\_STATUS register in Autonomous Mode and by elapsed time in Forced Mode. In Burst Mode, a subset of Autonomous Mode, all the expected data is valid.

#### 6.1 Output Field Utilization

In all modes, the CHAN\_LIST configuration determines how the data is stacked in the 26 byte output field. It is done on a first-come first-served basis, with the enabled lower channels taking up the lower addresses. When burst is enabled, the channel arrangement is just repeated to higher and higher addresses. See the example below.

-	lobal Section	Channel Specific Section of Parameter Table	
	CHAN_LIS	Output mode	
0	Bit 0	Chan 0	16
1	Bit 1	Chan 1	24
0	Bit 2	Chan 2	16
1	Bit 3	Chan 3	16
1	Bit 4 Chan 4		24
1	Bit 5 Chan 5		16
X	Bit 6 X		X
X	Bit 7	X	X

Packing of of these four channels in the output table is determined by the four enabled channels in the CHANNEL list above. This is independent of the IRQ\_ENABLE and IRQ\_STATUS

Figure 6.1. Output Table Data Packing

#### 6.2 Autonomous and Forced Modes

In Autonomous Mode, the user uses the timer fields in both the global and channels specific areas in order to set up the timing for repeated measurements. The user then sends the command to start these autonomous measurements repeatedly. When each channel's timer is tripped, the measurement for that channel is started. When the channel measurement completes, it is signaled by the IRQ\_STATUS bits and by an interrupt (if the interrupt is enabled). After that signal, the sensor restarts the channel timer and waits for it to trip and signal the next measurement. The host must read the data before the next reading is generated, or risk losing the reading or getting garbage data to sample smearing (reading data in the midst of it changing).

In Forced Mode, all measurements enabled in the CHAN\_LIST start as a result of a FORCE command and are only done once. If there are multiple channels enabled, then the measurements are done back-to-back starting with the lower number channel. The completion signaling is the same as for autonomous, the IRQ\_STATUS and interrupt if it is enabled. The logical difference is that all the enabled channels are always shown as simultaneously ready in the IRQ\_STATUS, whereas in Autonomous Mode this is not true. FORCE command only works on measurements which do not have a measurement counter selected in MEASCONFIGx.

Figure 6.2. IRQ_STATUS Shows Which Output Fields Have Valid Data	Figure 6.2	

#### 6.3 Burst Mode

Burst Mode is always used in Autonomous Mode.

The Burst Mode is enabled by the BURST register's bit 7. The burst register is in the global area of the parameter table. Bits 6:0 of the register define the number of readings to be made.

All channels set up in the CHAN\_LIST operate in this mode and they operate in unison governed by the MEASRATE register in the parameter table. The individual channel MEASCONFIGx.COUNTER\_INDEX [1:0] value is ignored.

The burst is started by the START command and may be paused by the PAUSE command. All measurements enabled in the CHAN\_LIST are done as a quick set then repeated after the delay determined by the MEASRATE register. The number of repeats are set by the BURST register.

The measurements called for by the enabled channels are done without an intervening delay, starting with the lower number channel and ending with the highest channel number.

The burst will proceed until it is complete or until the output buffer is full, after which an interrupt may be generated if enabled and the IRQ\_STATUS bit(s) associated with all the channels in the CHAN\_LIST will be set. The user has the time period until the next set of reads are finished to read back the data in the output field.

The output data will be stacked in the 26 bytes output data field and will be sequential. For example, if the CHAN\_LIST enables channels X, Y, and Z, then the data will be found in the output buffer as multiple sets: X1, Y1, Z1, X2, Y2, Z2... The fields X, Y, and Z are packed efficiently and are not necessarily the same length since they can be a mix of 16 and 24 bit values.

Since The CHAN\_LIST shows 4 active channels we see two sets of readings stacked one after another.

In burst mode the I2C HOSTOUT locations are updated simultaneously when the burst is done. Only then will the IRQ\_STATUS field be updates and an int generated (if the correct IRQ\_ENABLE bit(s) is set).

Figure 6.3. Burst Mode Example of Two Sets of Readings

#### **6.4 Interrupt Operation**

The INT output pin is asserted by the sensor when an enabled channel in the CHAN\_LIST (which has the corresponding bit in the RESET register) has finished. In Burst Mode, the interrupt is delayed until the number of readings is reached or the buffer is full.

When the host reads the IRQ\_STATUS register to learn which source generated the interrupt, the IRQ\_STATUS register is cleared automatically.

The most efficient method of extracting measurements from the Si1133 is an I<sup>2</sup>C Burst Read beginning at the IRQ\_STATUS register.

### 6.5 Timing of Channel Measurements

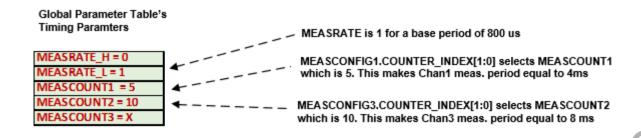

The timing of measurements has two aspects:

- 1. The length of time to take a measurement.
- 2. How frequently the measurement is taken.

The amount of time to take the measurement is controlled by factors like HW\_GAIN (which is really the integration time), SW\_GAIN, and the decimation rate setting.

Note: Each measurement is composed of two measurement times.

In an ALS measurement, two measurements are always taken and added together.

#### 7.2 Channel Specific Setup Areas of the Parameter Table

Below is the summary of the four-byte channel-specific area in the parameter table. There are six copies in the table corresponding to up to six tasks/channels assigned to the sensor. They are located between addresses 0x02 and 0x18 hex.

Table 7.3. Channel Specific Setup Areas of the Parameter Table

	7	6	5	4	3	2	1	0
ADCCONFIGx	RSRVD	DECIM_F	RATE[1:0]					
ADCSENSx	HSIG		SW_GAIN[2:0]			HW_GAIN[3:0]		
ADCPOSTx	RSRVD	24BIT_OUT	F	OSTSHIFT[2:0	0]	UNUSED	THRESH	_SEL[1:0]
MEASCONFIGx	COUNTER	_INDEX[1:0]			RSR\	/D(5:0)	-0	

The following figure illustrates how to use the channel-specific registers in the parameter table above.

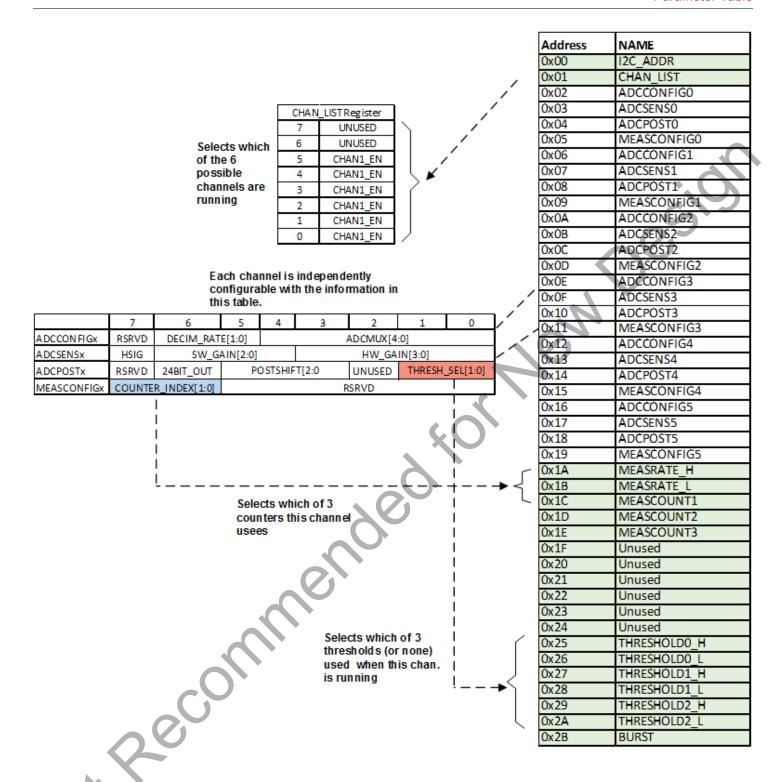

Figure 7.1. THRESH\_SEL, COUNTER\_INDEX Fields in Each Channel Specific Register Area Points to Global Area Register THRESHOLDx and MEASCOUNTx (Respectively)

**Note:** In the figure above, the counter selected (1, 2, or 3) defines the number of 800  $\mu$ s periods to have between readings when the channel runs. The threshold selected (0, 1, or 2) defines the threshold used.

# 9. Pin Descriptions

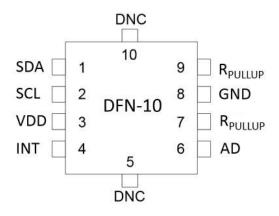

Figure 9.1. 10-Pin DFN

Table 9.1. Pin Descriptions

		VDD [	2 DFN-10 8 GND 3 7 R <sub>PULLUP</sub> 4 6 AD DNC Figure 9.1. 10-Pin DFN  Table 9.1. Pin Descriptions
Pin	Name	Туре	Description
1	SDA	Bidirectional	I <sup>2</sup> C Data.
2	SCL	Input	I <sup>2</sup> C Clock.
3	VDD	Power	Power Supply.  Voltage source.
4	INT	Bidirectional	Interrupt Output.  Open-drain interrupt output pin. Must be at logic level high during power-up sequence to enable low power operation.
5	DNC		Do Not Connect.  This pin is electrically connected to an internal Si1133 node. It should remain unconnected.
6	AD	Input	I <sup>2</sup> C Address Select.  It is sensed during startup. Pull up to VDD with 47 k Resistor for default I <sup>2</sup> C address (0x55). Pull down with 47 k Resistor to select alternate I <sup>2</sup> C address (0x52).
7	RPullup	Input	Resistor Pullup.  Always connect to V <sub>DD</sub> through a pull-up resistor.
8	GND	Power	Ground.  Reference voltage.
9	RPullup	Input	Resistor Pull-up.  Connect to V <sub>DD</sub> through a pull-up resistor when not in use.
10	DNC		Do Not Connect.  This pin is electrically connected to an internal Si1133 node. It should remain unconnected.

### 10. 10-Pin 2x2 mm DFN Module Outline

DFN Package Diagram Dimensions illustrates the package details for the Si1133 DFN package lists the values for the dimensions shown in the illustration.

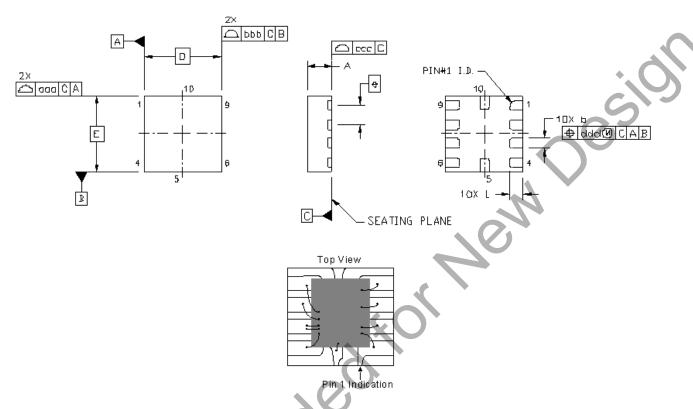

Figure 10.1. DFN Package Diagram Dimensions

Table 10.1. Package Diagram Dimensions

Dimension	Min	Nom	Max	
A	0.55	0.65	0.75	
b	0.20	0.25	0.30	
D		2.00 BSC.		
e		0.50 BSC.		
E		2.00 BSC.		
L	0.30	0.35	0.40	
aaa		0.10		
bbb	0.10			
ССС	0.08			
ddd	0.10			
Notes				

### Notes:

- 1. All dimensions shown are in millimeters (mm).
- 2. Dimensioning and Tolerance per ANSI Y14.5M-1994.

#### 11. 2x2 mm DFN Land Pattern

See the figure and table below for the suggested 2 x 2 mm DFN PCB land pattern.

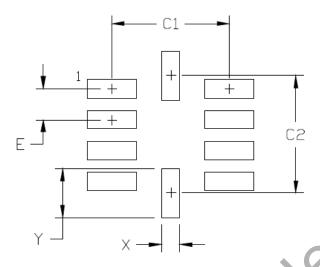

Figure 11.1. 2 x 2 mm DFN PCB Land Pattern

Table 11.1. Land Pattern Dimensions

Dimension	mm
C1	1.90
C2	1.90
E	0.50
Х	0.30
Y	0.80

#### Notes:

#### General

- 1. All dimensions shown are in millimeters (mm).
- 2. This Land Pattern Design is based on the IPC-7351 guidelines.
- 3. All dimensions shown are at Maximum Material Condition (MMC). Least Material Condition (LMC) is calculated based on a Fabrication Allowance of 0.05 mm.

#### Solder Mask Design

4. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 mm minimum, all the way around the pad.

#### Stencil Design

- 5. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
- 6. The stencil thickness should be 0.125 mm (5 mils).
- 7. The ratio of stencil aperture to land pad size should be 1:1 for all pads.

#### Card Assembly

- 8. A No-Clean, Type-3 solder paste is recommended.
- 9. The recommended card reflow profile is per the JEDEC/IPC J-STD-020D specification for Small Body Components.

### 12. Revision History

#### 12.1 Revision 0.9

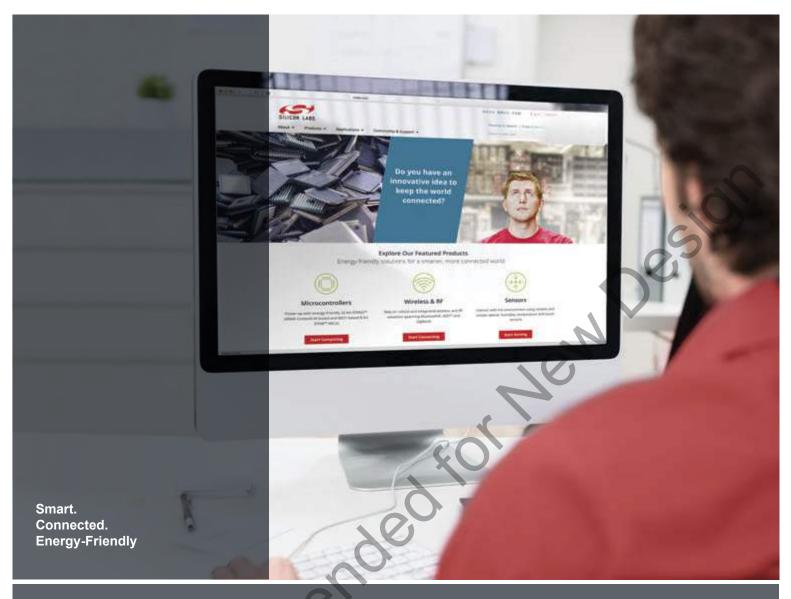

December 4th, 2015

· Initial release.

#### 12.2 Revision 0.91

February 11, 2016

- ot Recommended for New Desil. Corrected the value of I<sup>2</sup>C addresses to 0x55 and 0x52.
- · Corrected Device ID value to 0x33.
