

# GS9090A GenLINX® III 270Mb/s Deserializer

### **Key Features**

- SMPTE 259M-C compatible descrambling and NRZI to NRZ decoding (with bypass)
- DVB-ASI 8b/10b decoding
- Integrated line-based FIFO for data alignment/delay, clock phase interchange, DVB-ASI data packet extraction and clock rate interchange, and ancillary data packet extraction
- Integrated VCO and reclocker
- Single serial digital input buffer with wide input sensitivity and common mode point
- User selectable additional processing features including:
  - TRS, ANC data checksum, and EDH CRC error detection and correction
  - programmable ANC data detection
  - illegal code remapping
- Internal flywheel for noise immune H, V, F extraction
- Automatic standards detection and indication
- Enhanced Gennum Serial Peripheral Interface (GSPI)
- JTAG test interface
- Polarity insensitive for DVB-ASI and SMPTE signals
- +1.8V core power supply with optional +1.8V or +3.3V I/O power supply
- Small footprint (8mm x 8mm)
- Low power operation (typically 145mW)
- Pb-free and RoHS compliant

### **Applications**

- SMPTE 259M-C Serial Digital Interfaces
- DVB-ASI Serial Digital Interfaces

### Description

The GS9090A is a 270Mb/s reclocking deserializer with an internal FIFO. When used in conjunction with one of Gennum's SDI Cable Equalizers, a receive solution for SD-SDI and DVB-ASI applications can be realized.

In addition to reclocking and deserializing the input data stream, the GS9090A performs NRZI-to-NRZ decoding, descrambling as per SMPTE 259M-C, and word alignment when operating in SMPTE mode. When operating in DVB-ASI mode, the device will word align the data to K28.5 sync characters and 8b/10b decode the received stream.

The integrated reclocker features a very wide Input Jitter Tolerance, and is fully compatible with both SMPTE and DVB-ASI input streams.

The GS9090A includes a range of data processing functions such as error detection and correction, automatic standards detection, and EDH support. The device can also detect and extract SMPTE 352M payload identifier packets and independently identify the received video standard. This information is read from internal registers via the host interface port.

TRS errors, EDH CRC errors, and ancillary data checksum errors can all be detected and corrected. A single DATA\_ERROR pin is provided which is an inverted logical 'OR'ing of all detectable errors. Individual error status is stored in internal 'ERROR\_STATUS' registers.

The GS9090A also incorporates a video line-based FIFO. This FIFO may be used in four user-selectable modes to carry out tasks such as data alignment / delay, clock phase interchange, MPEG packet extraction and clock rate interchange, and ancillary data packet extraction.

Parallel data outputs are provided in 10-bit multiplexed format, with the associated parallel clock output signal operating at 27MHz.

The GS9090A is Pb-free, and the encapsulation compound does not contain halogenated flame retardant (RoHS compliant).

| Pin Number | Name         | Timing                   | Туре              | Description   |
|------------|--------------|--------------------------|-------------------|---|
| 46         | LOCKED       | Synchronous<br>with PCLK | Output            | STATUS SIGNAL OUTPUT<br>Signal levels are LVCMOS / LVTTL compatible.<br>The LOCKED signal will be HIGH whenever the device has correctl<br>received and locked to SMPTE compliant data in SMPTE mode or<br>DVB-ASI compliant data in DVB-ASI mode, or when the reclocker  |
|            |              |                          |                   | has achieved lock in Data-Through mode.<br>It will be LOW otherwise. When the signal is LOW, all digital outpu<br>signals will be forced to logic LOW levels.   |
| 47         | DVB_ASI      | Non<br>Synchronous       | Input /<br>Output | CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT<br>Signal levels are LVCMOS / LVTTL compatible.   |
|            |              |                          |                   | This pin and its function are only supported in Manual mode<br>(AUTO/MAN = LOW).<br>When set HIGH, the device will be configured to operate in<br>DVB-ASI mode. The <u>SMPTE_BYPASS</u> pin will be ignored.  |
|            |              |                          |                   | When set LOW, the device will not support the decoding or word alignment of received DVB-ASI data.  |
| 49         | SMPTE_BYPASS | Non<br>Synchronous       | Input /<br>Output | CONTROL SIGNAL INPUT / STATUS SIGNAL OUTPUT<br>Signal levels are LVCMOS / LVTTL compatible.   |
|            |              |                          |                   | This pin is an input set in Manual mode, and an output set by the device in Auto mode.  |
|            |              |                          |                   | Auto Mode (AUTO/MAN = HIGH):<br>The SMPTE_BYPASS signal will be HIGH only when the device has<br>locked to a SMPTE compliant data stream. It will be LOW<br>otherwise. When the signal is LOW, no I/O processing features are<br>available.   |
|            |              |                          |                   | Manual Mode (AUTO/MAN = LOW):<br>When set HIGH in conjunction with DVB_ASI = LOW, the device wi<br>be configured to operate in SMPTE mode. All I/O processing<br>features may be enabled in this mode.  |
|            |              |                          |                   | When the SMPTE_BYPASS pin is set LOW, the device will not<br>support the descrambling, decoding, or word alignment of<br>received SMPTE data. No I/O processing features will be available  |
| 50         | AUTO/MAN     | Non<br>Synchronous       | Input             | CONTROL SIGNAL INPUT<br>Signal levels are LVCMOS / LVTTL compatible.  |
|            |              |                          |                   | When set HIGH, the GS9090A will operate in Auto mode. The<br><u>SMPTE_BYPASS</u> pin becomes an output status signal set by the<br>device. In this mode, the GS9090A will automatically detect,<br>reclock, deserialize, and process SMPTE compliant input data.  |
|            |              |                          |                   | When set LOW, the GS9090A will operate in Manual mode. The DVB_ASI and <u>SMPTE_BYPASS</u> pins become input control signals. It this mode, the pins must be set for the correct reception of either SMPTE or DVB-ASI data. Manual mode also supports the reclockin and deserializing of data not conforming to SMPTE or DVB-ASI streams. |

| Pin Number | Name       | Timing             | Туре           | Description   |
|------------|------------|--------------------|----------------|---|
| 51         | FW_EN      | Non<br>Synchronous | Input          | CONTOL SIGNAL INPUT<br>Signal levels are LVCMOS / LVTTL compatible.   |
|            |            |                    |                | Used to enable or disable the noise immune flywheel of the device   |
|            |            |                    |                | When set HIGH, the internal flywheel is enabled. This flywheel is<br>used in the extraction of timing signals, the generation of TRS<br>signals, the automatic detection of video standards, and in manua<br>switch line lock handling. |
|            |            |                    |                | When set LOW, the internal flywheel is disabled. Timing based TR<br>errors will not be detected.  |
| 52         | FIFO_EN    | Non<br>Synchronous | Input          | CONTOL SIGNAL INPUT<br>Signal levels are LVCMOS / LVTTL compatible.   |
|            |            |                    |                | Used to enable / disable the internal FIFO.   |
|            |            |                    |                | When FIFO_EN is HIGH, the internal FIFO will be enabled. Data wil<br>be clocked out of the device on the rising edge of the RD_CLK<br>input pin if the FIFO is in video mode or DVB-ASI mode.   |
|            |            |                    |                | When FIFO_EN is LOW, the internal FIFO is bypassed and parallel data is clocked out on the rising edge of the PCLK output.  |
| 53         | VCO_VDD    | Analog             | Input<br>Power | Power supply connection for Voltage-Controlled-Oscillator.<br>Connect to +1.8V DC.  |
| 54         | LB_CONT    | Analog             | Input          | CONTROL SIGNAL INPUT  |
|            |            |                    |                | Control voltage to fine-tune the loop bandwidth of the PLL.   |
| 55         | VCO_GND    | Analog             | Input<br>Power | Ground connection for Voltage-Controlled-Oscillator. Connect to GND.  |
| 56         | LF+        | Analog             | Input          | Loop filter component connection. Connect to pin 1 (LF-) as shown in Typical Application Circuit (Part B) on page 68.   |
| -          | Center Pad | _                  | Power          | Connect to GND following recommendations in Recommended PCI<br>Footprint on page 70   |

#### NOTES

1. No signal to signal present, or a switch from another data rate to 270Mb/s.

2. Power supply noise 50mV  $_{\rm pp}$  at 15kHz, 100kHz, 1MHz sinusoidal modulation.

3. When the serial input to the GS9090A is removed, the PCLK output signal will continue to operate at 27MHz and the internal VCO will remain at this frequency within +/- 7.5% over the range -20°C to +85°C.

4. Timing includes the following outputs: DOUT[9:0], STAT[3:0]. When the FIFO is enabled, the outputs are measured with respect to RD\_CLK.

- JTAG Operation on page 64
- Device Power Up on page 65

# **3.1 Functional Overview**

The GS9090A is a 270Mb/s reclocking deserializer with an internal FIFO and programmable multi-function output port. The device has two basic modes of operation which determine precisely how SMPTE or DVB-ASI compliant input data streams are reclocked and processed.

In Auto mode (AUTO/MAN = HIGH), the GS9090A will automatically detect, reclock, deserialize, and process SD SMPTE 259M-C input data.

In Manual mode (AUTO/ $\overline{MAN}$  = LOW), the external device pins must be set for the correct reception of either SMPTE or DVB-ASI data. Manual mode also supports the reclocking and deserializing of 270Mb/s data not conforming to SMPTE or DVB-ASI streams.

The digital signal processing core implements several data processing functions including error detection and correction and automatic video standards detection. These features are all enabled by default, but may be individually disabled via internal registers accessible through the GSPI host interface.

The provided programmable multi-function output pins may be configured to output various status signals including H, V, and F timing, ancillary data detection, EDH detection, and a FIFO load pulse. The internal FIFO supports 4 modes of operation, which may be used for data alignment / delay, MPEG packet extraction, or ancillary data extraction.

The GS9090A contains a JTAG interface for boundary scan test implementations.

# **3.2 Serial Digital Input**

The GS9090A contains a current mode differential serial digital input buffer. The input buffer has internal  $50\Omega$  termination resistors, which are connected to ground via the TERM pin.

If the input signal is AC coupled to the device, the signal source common mode level will be set internally to typically 1.45V. If the input signal is DC coupled to the device, the internal biasing will be ignored. Please see AC Electrical Characteristics on page 13 for Common Mode range and swing characteristics.

# **3.3 Clock and Data Recovery**

The GS9090A contains an integrated clock and data recovery block. The function of this block is to lock to the input data stream, extract a clean clock, and retime the serial digital data to remove high frequency jitter.

# 3.3.1 Internal VCO and Phase Detector

The GS9090A uses an internal VCO and PFD as part of the internal clock and data recovery block's phase-locked loop. Each block requires a +1.8V DC power supply, which is supplied via the VCO\_VDD / VCO\_GND and PLL\_VDD / PLL\_GND pins.

# 3.4 Serial-To-Parallel Conversion

The retimed data and phase-locked clock signals from the internal clock and data recovery block are fed to the serial-to-parallel converter. The function of this block is to extract 10-bit parallel data words from the reclocked serial data stream and simultaneously present them to the SMPTE and DVB-ASI word alignment blocks.

# 3.5 Modes Of Operation

The GS9090A has two basic modes of operation: Auto mode and Manual mode. Auto mode is enabled when the AUTO/MAN pin is set HIGH, and Manual mode is enabled when the AUTO/MAN pin is set LOW. As indicated in Figure 3-1. DVB\_ASI and data-through are only supported in Manual mode.

Figure 3-1: GS9090A's Modes of Operation

## 3.5.1 Lock Detect

Once the internal reclocker has locked to the received serial digital data stream, the lock detect block of the GS9090A searches for the appropriate sync words, and indicates via the LOCKED output pin when the device has successfully achieved lock. The LOCKED pin is designed to be stable. It will not toggle during the locking process, nor will it glitch during a synchronous switch.

Lock detection is a continuous process, which begins after a system reset and continues until the device is powered down or held in reset. This process is summarized in Figure 3-2.

### Figure 3-2: Lock Detection Process

The lock detection algorithm first determines if a valid serial digital input signal has been presented to the device by sampling the internal carrier\_detect signal. When the serial data input is considered invalid the LOCKED pin will be set LOW, and all device outputs will be forced LOW, except PCLK. The PCLK output frequency will be 27MHz +/-7.5% over the temperature range of -20°C to +85°C.

If a valid serial digital input signal has been detected, and the device is in Auto mode, the lock algorithm will attempt to detect the presence of SMPTE TRS words. Assuming that a valid 270Mb/s SMPTE signal has been applied to the device, the LOCKED pin will be set HIGH and the synchronous and asynchronous lock times will be as listed in the AC Electrical Characteristics table.

In Manual mode, the <u>SMPTE\_BYPASS</u> and DVB\_ASI pins must be set appropriately so that the lock detect block will search for either SMPTE TRS or DVB-ASI sync words. Synchronous and asynchronous lock times are also listed in the <u>AC Electrical</u> Characteristics table.

NOTE: The PCLK output will continue to operate at 27MHz +/- 7.5% during the lock detection process. Only when the device is locked (LOCKED = HIGH) will the PCLK output an accurate 27MHz signal.

For SMPTE and DVB-ASI inputs, the lock detect block will only assert the LOCKED output pin HIGH if (1) the reclocker has locked to the input data stream, and (2) TRS or DVB-ASI sync words have been correctly identified.

For serial inputs that do not conform to SMPTE or DVB-ASI formats, one of the following will occur once the reclocker has locked:

- 1. In Manual mode, data will be passed directly to the parallel outputs without any further processing taking place and the LOCKED signal will be asserted HIGH if and only if the SMPTE\_BYPASS and DVB\_ASI input pins are set LOW (see Data-Through functionality on page 30); or
- 2. In Auto mode, the LOCKED signal will be asserted LOW, the parallel outputs will be set to logic LOW, and the <u>SMPTE\_BYPASS</u> signal will also be set LOW.

If the internal reclocker does not lock to the input, the internal pll\_lock signal will be LOW, and the lock detect block will not search for sync words. The LOCKED signal will be set LOW, and all device outputs except PCLK will be forced LOW. The PCLK output frequency will be 27MHz +/- 7.5% over the temperature range of -20°C to +85°C.

## 3.5.2 Auto Mode

Recall that the GS9090A is in Auto mode when the AUTO/MAN input pin is set HIGH. In this mode, <u>SMPTE\_BYPASS</u> becomes an output status pin. <u>Table 3-1</u> shows the status of this pin when different serial digital video signals are applied.

|           | • | 5            |
|-----------|---|--------------|
|           |   | Pin Settings |
| Format    |   | SMPTE_BYPASS |
| SD SMPTE  |   | HIGH         |
| NOT SMPTE |   | LOW          |

### Table 3-1: Auto Mode Output Status Signals

## 3.5.3 Manual Mode

Recall that the GS9090A is in Manual mode when the AUTO/ $\overline{MAN}$  input pin is set LOW. In this mode the  $\overline{SMPTE}$  BYPASS and DVB\_ASI pins become input signals, and the operating mode of the device is determined by setting these pins as shown in Table 3-2

|  | Pin Settings |         |  |
|--|--------------|---------|--|
| Format                                       | SMPTE_BYPASS | DVB_ASI |  |
| SD SMPTE                                     | HIGH         | LOW     |  |
| DVB-ASI                                      | Х            | HIGH    |  |
| NOT SMPTE OR DVB-ASI<br>(Data-Through mode)* | LOW          | LOW     |  |

### Table 3-2: Manual Mode Input Status Signals

\*NOTE: See Data-Through functionality on page 30 for more detail on Data-Through mode

# **3.6 SMPTE Functionality**

The GS9090A enters SMPTE mode once the device has detected SMPTE TRS sync words and locked to the input data stream as described in Lock Detect on page 23. The GS9090A will remain in SMPTE mode until such time that SMPTE TRS sync words fail to be detected.

The lock detect block may also drop out of SMPTE mode under any of the following conditions:

- SMPTE\_BYPASS is asserted LOW in Manual mode
- RESET is asserted LOW
- LOCKED is LOW (i.e. the device loses lock to the input signal)

TRS word detection is a continuous process, and the device will identify both 8-bit and 10-bit TRS words.

In Auto mode, the GS9090A sets the <u>SMPTE\_BYPASS</u> pin HIGH to indicate that it has locked to a SMPTE input data stream. When operating in Manual mode, the DVB\_ASI pin must be set LOW and the <u>SMPTE\_BYPASS</u> pin HIGH in order to enable SMPTE operation.

## **3.6.1 SMPTE Descrambling and Word Alignment**

After serial-to-parallel conversion, the internal 10-bit data bus is fed to the SMPTE descramble and word alignment internal block. The function of this block is to carry out NRZI-to-NRZ decoding, descrambling according to SMPTE 259M-C, and word alignment of the data to the TRS sync words.

NOTE: When 8-bit data is embedded in the 10-bit SMPTE signal, the two LSBs (DOUT[1:0]) must be set to zero for word alignment to work correctly.

Word alignment occurs when two consecutive valid TRS words (SAV and EAV inclusive) with the same bit alignment have been detected (1 video line).

In normal operation, re-synchronization of the word alignment process will only take place when two consecutive identical TRS word positions have been detected. When automatic or manual switch line lock handling occurs (see Switch Line Lock Handling on page 27), word alignment re-synchronization will occur on the next received TRS code word.

The device will drop out of SMPTE mode, only after 6 consecutive missing TRS timing words.

# 3.6.2 Internal Flywheel

The GS9090A has an internal flywheel for the generation of internal / external timing signals, the detection and correction of certain error conditions, and the automatic detection of video standards. The flywheel is only operational in SMPTE mode.

The flywheel 'learns' the video standard by monitoring the horizontal and vertical reference information contained in the TRS ID words of the received video stream. Full synchronization of the flywheel to the received video standard therefore requires one complete video frame.

Once synchronization has been achieved, the flywheel will continue to monitor the received TRS timing information to maintain synchronization.

The FW\_EN input pin controls the synchronization mechanism of the flywheel. When this input signal is LOW, the flywheel will re-synchronize all pixel and line based counters on every received TRS ID word.

When FW\_EN is held HIGH, re-synchronization of the pixel and line based counters will take place after 3 consecutive video lines with identical TRS timing are identified. This provides a measure of noise immunity for output timing signal generation.

The flywheel will be disabled should the LOCKED signal or  $\overline{\text{RESET}}$  signal be LOW. This will occur regardless of the setting of the FW\_EN pin.

# 3.6.3 Switch Line Lock Handling

The principle of switch line lock handling is that the switching of synchronous video sources will only disturb the horizontal timing and alignment of the stream, whereas the vertical timing remains in synchronization.

To account for the horizontal disturbance caused by a synchronous switch, it is necessary to re-synchronize the flywheel immediately after the switch has taken place. Rapid re-synchronization of the GS9090A to the new video standard can be achieved by controlling the flywheel using the FW\_EN pin.

At every PCLK cycle the device samples the FW\_EN pin. When the FW\_EN pin is set LOW anywhere within the active line, the flywheel will re-synchronize immediately to the next TRS word.

The ability to manually re-synchronize the flywheel is also important when switching asynchronous sources or to implement other non-standardized video switching functions.

The GS9090A also implements automatic switch line lock handling. By utilizing both the synchronous switch point defined in SMPTE RP168, and the automatic video standards detect function, the device automatically re-synchronizes the flywheel at the switch point. This will occur whether or not the device has detected TRS word errors. Word alignment re-synchronization will also take place at this time.

Automatic switch line lock handling will occur regardless of the setting of the FW\_EN pin.

The switch line is as defined in Table 3-3.

| System | Video Format        | Sampling | Signal<br>Standard | Parallel<br>Interface | Serial Interface | Switch Line<br>Number |
|--------|---------------------|----------|--------------------|-----------------------|------------------|-----------------------|
| 525    | 720x483/59.94 (2:1) | 4:2:2    | 125M               | 125M                  | 259M-C           | 10, 273               |
| 625    | 720x576/50 (2:1)    | 4:2:2    | BT.656             | 125M                  | 259M-C           | 6, 319                |

### Table 3-3: Switch Line Position for 270Mb/s Digital Systems

## 3.6.4 HVF Timing Signal Generation

The GS9090A extracts critical timing parameters from either the received TRS signals (FW\_EN = LOW) or from the internal flywheel-timing generator (FW\_EN = HIGH).

Horizontal blanking period (H), vertical blanking period (V), and field odd / even timing (F) are extracted and are available for output on any of the multi-function output port pins, if so programmed (see Programmable Multi-Function Outputs on page 57).

The H signal timing is configurable via the H\_CONFIG bit of the internal IOPROC\_DISABLE register as either active line-based blanking, or TRS-based blanking (see Table 3-14 in Error Correction and Insertion on page 44).

The default setting of this bit (after  $\overline{\text{RESET}}$  has been asserted) is LOW.

Active line-based blanking is enabled when the H\_CONFIG bit is set LOW. In this mode, the H output is HIGH for the entire horizontal blanking period, including the EAV and SAV TRS words. This is the default H timing used by the device.

When H\_CONFIG is set HIGH, TRS based blanking is enabled. In this case, the H output will be HIGH for the entire horizontal blanking period as indicated by the H bit in the received TRS ID words.

The timing of these signals is shown in Figure 3-3.

NOTE 1: When the internal FIFO is configured for video mode, the H, V, and F signals will be timed to the data output from the FIFO (see Video Mode on page 47).

NOTE 2: When the GS9090A is configured for Low-latency mode, the H, V, and F output timing will be TRS-based only as shown in Low-latency Mode on page 59. Active

line-based timing is not available in this mode, and the setting of the H\_CONFIG host interface bit will be ignored.

H\_CONFIG = LOW (Default)

Figure 3-3: H,V,F Timing

# **3.7 DVB-ASI Functionality**

The lock detect block may drop out of DVB-ASI mode under the following conditions:

- RESET is asserted LOW
- Both AUTO/MAN and DVB\_ASI are asserted LOW
- LOCKED pin is LOW (i.e. the device loses lock to the input signal)

DVB\_ASI functionality is only supported in Manual mode. When operating in Manual mode, the DVB\_ASI pin must be set HIGH to enable DVB-ASI operation. The <u>SMPTE\_BYPASS</u> pin will be ignored.

DVB-ASI functionality is only supported up to a transport stream data rate of 35Mb/s. To support higher transport stream data rates, please refer to the GS9090B.

## 3.7.1 DVB-ASI 8b/10b Decoding

After serial-to-parallel conversion, the internal 10-bit data bus is fed to the DVB-ASI 8b/10b decode and word alignment block. The function of this block is to word align the data to the K28.5 sync characters, and 8b/10b decode and bit-swap the data to achieve bit alignment with the data outputs.

The extracted 8-bit data will be presented to DOUT [7:0], bypassing all internal SMPTE mode data processing.

## **3.7.2 Status Signal Outputs**

In DVB-ASI mode, the DOUT9 and DOUT8 pins will be configured as DVB-ASI status signals WORDERR and SYNCOUT respectively.

SYNCOUT will be HIGH whenever a K28.5 sync character is present on the output. WORDERR will be HIGH whenever the device has detected an illegal code word or there is a running disparity error.

# 3.8 Data-Through functionality

The GS9090A may be configured to operate as a simple serial-to-parallel converter. In this mode, the device presents data to the output data bus without performing any decoding, descrambling, or word-alignment.

Data-Through functionality is enabled only when the AUTO/MAN, SMPTE\_BYPASS, and DVB\_ASI input pins are set LOW. Under these conditions, the lock detect block allows 270Mb/s input data not conforming to SMPTE or DVB-ASI streams to be reclocked and deserialized. If the device is in Data-Through mode, and the internal reclocker locks to the data stream, the LOCKED pin will be set HIGH.

If the AUTO/MAN pin is not set LOW, the GS9090A will set the SMPTE\_BYPASS to logic LOW if presented with a data stream without SMPTE TRS ID words. In addition, the LOCKED pin and data bus output pins will be forced LOW.

# **3.9 Additional Processing Features**

The GS9090A contains additional processing features that are available in SMPTE mode only (see SMPTE Functionality on page 26).

## 3.9.1 FIFO Load Pulse

To aid in the implementation of auto-phasing and line synchronization functions, the GS9090A will generate a FIFO load pulse to reset line-based FIFO storage. This FIFO\_LD signal is available for output on one of the multi-function output port pins, if so programmed (see Programmable Multi-Function Outputs on page 57).

The FIFO\_LD pulse will normally be HIGH, but will go LOW for one PCLK period, thereby generating a FIFO write reset signal.

By default, the FIFO load pulse will be generated such that it is co-timed to the SAV XYZ code word presented to the output data bus. This co-timing ensures that the next PCLK cycle will correspond with the first active sample of the video line.

NOTE: When the internal FIFO of the GS9090A is set to operate in video mode, the FIFO\_LD pulse can be used to drive the RD\_RESET input to the device (see Video Mode on page 47).

Figure 3-4 shows the default timing relationship between the FIFO\_LD signal and the output video data.

Figure 3-4: FIFO\_LD Pulse Timing

### 3.9.1.1 Programmable FIFO Load Position

The position of the FIFO\_LD pulse can be moved in PCLK increments from its default position to a maximum of one full line. The offset number of PCLK's must be programmed in the FIFO\_LD\_POSITION[12:0] internal register (address 28h), via the host interface.

The FIFO\_LD\_POSITION[12:0] register is designed to accommodate the longest SD line length. If the user programs a value greater than the maximum line length at the operating SD standard, the FIFO\_LD pulse will not be generated.

After a device reset, the FIFO\_LD\_POSITION[12:0] register is set to zero and the FIFO\_LD pulse will assume the default timing.

# 3.9.2 Ancillary Data Detection and Indication

The GS9090A will detect all types of ancillary data in either the vertical or horizontal data spaces. The ANC\_DETECT status signal is provided to indicate the position of ancillary data in the output data stream. This signal is available for output on the multi-function output port pins, if so programmed (see Programmable Multi-Function Outputs on page 57).

The ANC\_DETECT status signal is synchronous with PCLK and can be used as a clock enable to external logic, or as a write enable to an external FIFO or other memory device. The ANC\_DETECT signal will be asserted HIGH whenever ancillary data is detected in the video data stream (see Figure 3-5). Both 8-bit and 10-bit ancillary data preambles will be detected by the GS9090A.

NOTE 1: When the internal FIFO is configured for video mode, the ANC\_DETECT signal will be timed to the data output from the FIFO (see Video Mode on page 47).

NOTE 2: For performance in low latency mode, see Low-latency Mode on page 59.

Figure 3-5: ANC\_DETECT Status Signal

### 3.9.2.1 Programmable Ancillary Data Detection

Although the GS9090A will detect all types of ancillary data by default, it also allows specific programming of up to five different ancillary data types for detection. This is accomplished by setting the ANC\_TYPE registers via the host interface (see Table 3-4).

For each data type to be detected, the host interface must program the DID and/or SDID of the ancillary data type of interest. The GS9090A will compare the received DID and/or SDID with the programmed values and assert ANC only if an exact match is found. The same timing shown in Figure 3-5 will be used.

If any DID or SDID value is set to zero in the ANC\_TYPE register, no comparison or match will be made for that value. For example, if the DID is programmed but the SDID is set to zero, the device will detect all ancillary data types matching the DID value, regardless of the SDID. If both DID and SDID values are non-zero, then the received ancillary data type must match both the DID and SDID cases before the device will assert ANC\_DETECT HIGH.

In the case where all five DID and SDID values are set to zero, the GS9090A will detect all ancillary data types. This is the default setting after a device reset.

Where one or more, but less than five, DID and/or SDID values have been programmed, then only those matching ancillary data types will be detected and indicated.

NOTE: See SMPTE 291M for a definition of ancillary data terms.

| Register Name              | Bit  | Name            | Description   | R/W | Default |
|----------------------------|------|-----------------|---|-----|---------|
| ANC_TYPE 1<br>Address: 0Ah | 15-8 | ANC_TYPE1[15:8] | Used to program the DID for ancillary data detection at ANC_DETECT output   | R/W | 0       |
|                            | 7-0  | ANC_TYPE1[7:0]  | Used to program the SDID for ancillary data detection at ANC_DETECT output. Should be set to zero if no SDID is present in the ancillary data packet to be detected.          | R/W | 0       |
| ANC_TYPE 2<br>Address: 0Bh | 15-8 | ANC_TYPE2[15:8] | Used to program the DID for ancillary data detection at ANC_DETECT output   | R/W | 0       |
|                            | 7-0  | ANC_TYPE2[7:0]  | Used to program the SDID for ancillary data detection at ANC_DETECT output. Should be set to zero if no SDID is present in the ancillary data packet to be detected.          | R/W | 0       |
| ANC_TYPE 3<br>Address: 0Ch | 15-8 | ANC_TYPE3[15:8] | Used to program the DID for ancillary data detection at ANC_DETECT output   | R/W | 0       |
|                            | 7-0  | ANC_TYPE3[7:0]  | Used to program the SDID for ancillary data<br>detection at ANC_DETECT output. Should be<br>set to zero if no SDID is present in the<br>ancillary data packet to be detected. | R/W | 0       |
| ANC_TYPE 4<br>Address: 0Dh | 15-8 | ANC_TYPE4[15:8] | Used to program the DID for ancillary data detection at ANC_DETECT output   | R/W | 0       |
|                            | 7-0  | ANC_TYPE4[7:0]  | Used to program the SDID for ancillary data detection at ANC_DETECT output. Should be set to zero if no SDID is present in the ancillary data packet to be detected.          | R/W | 0       |
| ANC_TYPE 5<br>Address: 0Eh | 15-8 | ANC_TYPE5[15:8] | Used to program the DID for ancillary data detection at ANC_DETECT output   | R/W | 0       |
|                            | 7-0  | ANC_TYPE5[7:0]  | Used to program the SDID for ancillary data detection at ANC_DETECT output. Should be set to zero if no SDID is present in the ancillary data packet to be detected.          | R/W | 0       |

### Table 3-4: Host Interface Description for Programmable Ancillary Data Type registers

## 3.9.3 EDH Packet Detection

The GS9090A will determine if EDH packets are present in the incoming video data and assert the EDH\_DETECT output status signal appropriately.

EDH\_DETECT will be set HIGH when EDH packets have been detected and will remain HIGH until EDH packets are no longer present. The signal will be set LOW at the end of the vertical blanking (falling edge of V) if an EDH packet has not been received and detected during vertical blanking.

EDH\_DETECT is available for output on the multi-function output port pins, if so programmed (see Programmable Multi-Function Outputs on page 57). Additionally, the EDH\_DETECT bit is stored in the DATA\_FORMAT register at address 04h (see Table 3-7).

## 3.9.4 EDH Flag Detection

As described in EDH Packet Detection on page 33, the GS9090A can detect EDH packets in the received data stream. The EDH flags for ancillary data, active picture, and full field areas are extracted from the detected EDH packets and placed in the EDH\_FLAG\_IN register of the device (Table 3-5).

When the EDH\_FLAG\_UPDATE bit in the DATA\_FORMAT register (Table 3-7) is set HIGH, the GS9090A will update the ancillary data, full field, and active picture EDH flags according to SMPTE RP165. The updated EDH flags are placed in the EDH\_FLAG\_OUT register (Table 3-6). The EDH packet output from the device will contain the updated flags.

One set of flags is provided for both fields 1 and 2. Field 1 flag data will be overwritten by field 2 flag data.

When no EDH packets are detected (EDH\_DETECT = LOW), the UES flags in the EDH\_FLAG\_OUT register will be set HIGH to signify that the received signal does not support the error detection practice. These flags are set regardless of the setting of the EDH\_FLAG\_UPDATE bit.

NOTE: When EDH\_FLAG\_UPDATE is LOW with EDH packets in the video stream, the content of the EDH\_FLAG\_OUT register is not valid and should be ignored.

Both EDH\_FLAG registers may be read by the host interface at any time during the received frame except on the lines defined in SMPTE RP165 where these flags are updated.

The GS9090A will also extract the CRC valid or 'V' bit for both active picture and full field CRCs. The AP\_CRC\_V bit in the DATA\_FORMAT register provides the active picture CRC valid bit status, and the FF\_CRC\_V bit provides the full field CRC valid bit status (see Table 3-7). When EDH\_DETECT = LOW, these bits will be cleared.

The flag register values remain set until overwritten by the decoded flags in the next received EDH packet in the following field. When no EDH packet is detected during vertical blanking, the flag registers will be cleared at the end of the vertical blanking period.

| Register Name               | Bit | Name       | Description   | R/W | Default |
|-----------------------------|-----|------------|---|-----|---------|
| EDH_FLAG_IN<br>Address: 02h | 15  | -          | Not Used  | -   | _       |
|                             | 14  | ANC-UES_IN | Ancillary Unknown Error Status Flag                         | R   | 0       |
|                             | 13  | ANC-IDA_IN | Ancillary Internal device error Detected Already Flag.      | R   | 0       |
|                             | 12  | ANC-IDH_IN | Ancillary Internal device error Detected Here Flag.         | R   | 0       |
|                             | 11  | ANC-EDA_IN | Ancillary Error Detected Already Flag.                      | R   | 0       |
|                             | 10  | ANC-EDH_IN | Ancillary Error Detected Here Flag.                         | R   | 0       |
|                             | 9   | FF-UES_IN  | Full Field Unknown Error Status Flag.                       | R   | 0       |
|                             | 8   | FF-IDA_IN  | Full Field Internal device error Detected Already Flag.     | R   | 0       |
|                             | 7   | FF-IDH_IN  | Full Field Internal device error Detected Here Flag.        | R   | 0       |
|                             | 6   | FF-EDA_IN  | Full Field Error Detected Already Flag.                     | R   | 0       |
|                             | 5   | FF-EDH_IN  | Full Field Error Detected Here Flag.                        | R   | 0       |
|                             | 4   | AP-UES_IN  | Active Picture Unknown Error Status Flag.                   | R   | 0       |
| -                           | 3   | AP-IDA_IN  | Active Picture Internal device error Detected Already Flag. | R   | 0       |
|                             | 2   | AP-IDH_IN  | Active Picture Internal device error Detected Here<br>Flag  | R   | 0       |
|                             | 1   | AP-EDA_IN  | Active Picture Error Detected Already Flag.                 | R   | 0       |
|                             | 0   | AP-EDH_IN  | Active Picture Error Detected Here Flag.                    | R   | 0       |

## Table 3-5: Host Interface Description for EDH Flag Registers

| Register Name                | Bit | Name    | Description   | R/W | Default |
|------------------------------|-----|---------|---|-----|---------|
| EDH_FLAG_OUT<br>Address: 03h | 15  | -       | Not Used  | -   | -       |

## Table 3-6: Host Interface Description for EDH Flag Registers

| Register<br>Name | Bit   | Name             | Description  | R/W | Default |
|------------------|-------|------------------|--|-----|---------|
| DATA_FORMAT      | 15-12 | -                | Not Used   | -   | -       |
|                  | 11    | EDH_FLAG_UPDATE  | When set HIGH, the device will update the ancillary<br>data, full field, and active picture EDH flags<br>according to SMPTE RP165.   | R/W | 0       |
|                  | 10    | AP_CRC_V         | Active Picture CRC Valid bit.  | R   | 0       |
|                  | 9     | FF_CRC_V         | Full Field CRC Valid bit.  | R   | 0       |
|                  | 8     | EDH_DETECT       | Set HIGH by the device when EDH packets are detected in the incoming video data.   | R   | 0       |
|                  | 7     | VERSION_352M     | Indicates whether decoded SMPTE 352M packet is version 0 or version 1. See SMPTE 352M Payload Identifier on page 37.   | R   | 0       |
|                  | 6-5   | _                | Not Used   | -   | -       |
|                  | 4     | STD_LOCK         | Standard Lock bit. This bit will be set HIGH when the<br>flywheel has achieved full synchronization to the<br>received video standard. See Automatic Video<br>Standard and Data Format Detection on page 38. | R   | 0       |
|                  | 3-0   | DATA_FORMAT[3:0] | Displays the data format being carried on the serial digital interface. See Video Standard Indication on page 39.  | R   | 0       |

## Table 3-7: Host Interface Description for Data Format Register

## 3.9.5 SMPTE 352M Payload Identifier

The GS9090A can receive and detect the presence of the SMPTE 352M payload identifier ancillary data packet. This four word payload identifier packet may be used to indicate the transport mechanism, frame rate and line scanning / sampling structure.

Upon reception of this packet, the device will extract the four words describing the video format being transported and make this information available to the host interface via the four VIDEO\_FORMAT 8 bit registers (Table 3-8). The device will also indicate the version of the payload packet in bit 7 of the DATA\_FORMAT register (Table 3-7). When this bit is set HIGH the received SMPTE 352M packet is version 1, otherwise it is version 0.

The VIDEO\_FORMAT registers will only be updated if the received checksum is the same as the locally calculated checksum.

NOTE: The VIDEO\_FORMAT registers will not be updated with 352M payload data if the packets are not on the correct video line (as stated in this standard).

These registers will be cleared to zero, indicating an undefined format, if the device loses lock to the input data stream (LOCKED = LOW), or if the SMPTE\_BYPASS pin is asserted LOW. This is also the default setting after a device reset.

| Register Name                      | Bit  | Name              | Description  | R/W | Default |
|------------------------------------|------|-------------------|--|-----|---------|
| VIDEO_FORMAT_OUT_B<br>Address: 10h | 15-8 | SMPTE 352M Byte 4 | Data will be available in this register when<br>Video Payload Identification Packets are<br>detected in the data stream. | R   | 0       |
|                                    | 7-0  | SMPTE 352M Byte 3 | Data will be available in this register when<br>Video Payload Identification Packets are<br>detected in the data stream. | R   | 0       |
| VIDEO_FORMAT_OUT_A<br>Address: 0Fh | 15-8 | SMPTE 352M Byte 2 | Data will be available in this register when<br>Video Payload Identification Packets are<br>detected in the data stream. | R   | 0       |
|                                    | 7-0  | SMPTE 352M Byte 1 | Data will be available in this register when<br>Video Payload Identification Packets are<br>detected in the data stream. | R   | 0       |

## Table 3-8: Host Interface Description for SMPTE 352M Payload Identifier Registers

## 3.9.6 Automatic Video Standard and Data Format Detection

The GS9090A can independently detect the input video standard and data format by using the timing parameters extracted from the received TRS ID words. Total samples per line, active samples per line, total lines per field/frame, and active lines per field/frame are all calculated and presented to the host interface via the RASTER\_STRUCTURE registers (Table 3-9).

Also associated with the RASTER\_STRUCTURE registers is the status bit, STD\_LOCK. The GS9090A will set STD\_LOCK HIGH when the flywheel has achieved full synchronization to the received video standard. STD\_LOCK is stored in the DATA\_FORMAT register (Table 3-7).

The four RASTER\_STRUCTURE registers, as well as the STD\_LOCK status bit will default to zero after a device reset. They will also default to zero if the device loses lock to the input data stream (LOCKED = LOW), or if the <u>SMPTE\_BYPASS</u> pin is asserted LOW.

#### Table 3-9: Host Interface Description for Raster Structure Registers

| Register Name                     | Bit   | Name                    | Description            | R/W | Default |
|-----------------------------------|-------|-------------------------|------------------------|-----|---------|
| RASTER_STRUCTURE1                 | 15-11 | _                       | Not Used               | _   | -       |
| Address: 11h                      | 10-0  | RASTER_STRUCTURE1[10:0] | Total Lines Per Frame  | R   | 0       |
| RASTER_STRUCTURE2<br>Address: 12h | 15-13 | -                       | Not Used               | _   | _       |
|                                   | 12-0  | RASTER_STRUCTURE2[12:0] | Total Words Per Line   | R   | 0       |
| RASTER_STRUCTURE3                 | 15-13 | -                       | Not Used               | _   | _       |
| Address: 13h                      | 12-0  | RASTER_STRUCTURE3[12:0] | Words Per Active Line  | R   | 0       |
| RASTER_STRUCTURE4                 | 15-11 | _                       | Not Used               | _   | -       |
| Address: 14h                      | 10-0  | RASTER_STRUCTURE4[10:0] | Active Lines Per Field | R   | 0       |

### 3.9.6.1 Video Standard Indication

As well as detecting the video standard, the GS9090A can extract the data format being carried on the serial digital interface (i.e. SDTI, SDI, or DVB-ASI).

This information is represented by bits 0 to 3 of the DATA\_FORMAT register (Table 3-7), which may be read via the host interface. DATA\_FORMAT[3:0] register codes are shown in Table 3-10.

The DATA\_FORMAT[3:0] register defaults to Fh (undefined) after a system reset. The register will also be set to its default value if the device is not locked (LOCKED = LOW), or if both <u>SMPTE\_BYPASS</u> and DVB\_ASI pins are LOW.

| Data Format[3:0] | Data Format                    | Applicable Standards |
|------------------|--------------------------------|----------------------|
| 0h               | SDTI DVCPRO - No ECC           | SMPTE 321M           |
| 1h               | SDTI DVCPRO - ECC              | SMPTE 321M           |
| 2h               | SDTI DVCAM                     | SMPTE 322M           |
| 3h               | SDTI CP                        | SMPTE 326M           |
| 4h               | Other SDTI fixed block size    | -                    |
| 5h               | Other SDTI variable block size | -                    |
| 6h               | SDI                            | -                    |
| 7h               | DVB-ASI                        | -                    |
| 8h ~ Eh          | Reserved                       | -                    |
| Fh               | Unknown data format            | -                    |

| Table 3-10: D | Data Format | Register | Codes |
|---------------|-------------|----------|-------|
|---------------|-------------|----------|-------|

## 3.9.7 Error Detection and Indication

The GS9090A contains a number of error detection functions to enhance operation of the device when operating in SMPTE mode. These functions, except lock error detection, will not be available in DVB-ASI mode (DVB-ASI Functionality on page 29) or Data-Through mode (Data-Through functionality on page 30).

The device maintains an error status register at address 01h called ERROR\_STATUS. Each type of error has a specific flag or bit in this register that is set HIGH whenever that error is detected (Table 3-11).

All bits in the ERROR\_STATUS register, except the LOCK\_ERR bit, will be cleared at the start of each video field or when read by the host interface, whichever condition occurs first.

All bits, with the exception of the LOCK\_ERR, will also be cleared if a change in the video standard is detected, or under the following conditions:

- LOCKED is asserted LOW
- <u>SMPTE\_BYPASS</u> is asserted LOW in Manual mode

The whole ERROR\_STATUS register, including the LOCK\_ERR bit, will be set LOW during a system reset (RESET = LOW).

In addition to the ERROR\_STATUS register, a register called ERROR\_MASK is included to select the specific error conditions that will be detected (Table 3-12). There is one bit in the ERROR\_MASK register for each type of error represented in the ERROR\_STATUS register.

The bits of the ERROR\_MASK register will default to '0' after a device reset, thus allowing all error types to be detected. The host interface may disable individual error detection by setting the corresponding bit HIGH in this register.

Error conditions are also indicated via the status signal pin DATA\_ERROR. This output pin is an inverted logical 'OR'ing of each error status flag stored in the ERROR\_STATUS register. DATA\_ERROR is normally HIGH, but will be set LOW by the device when an error condition that has not been masked is detected.

| Register Name  | Bit  | Name       | Description   | R/W | Default |
|----------------|------|------------|---|-----|---------|
| ERROR_STATUS   | 15-7 | _          | Not Used  | _   | -       |
| Address: 01h 6 | 6    | VD_STD_ERR | Video Standard Error Flag. Set HIGH when a<br>mismatch between the received SMPTE 352M<br>packets (version 1 or version 0) and the<br>calculated video standard occurs. | R   | 0       |
|                | 5    | FF_CRC_ERR | Full Field CRC Error Flag. Set HIGH when a Full<br>Field (FF) CRC mismatch has been detected in<br>Field 1 or 2   | R   | 0       |
|                | 4    | AP_CRC_ERR | Active Picture CRC Error Flag. Set HIGH when<br>an Active Picture (AP) CRC mismatch has been<br>detected in Field 1 or 2.   | R   | 0       |
|                | 3    | LOCK_ERR   | Lock Error Flag. Set HIGH whenever the<br>LOCKED pin is LOW (indicating the device is not<br>correctly locked).   | R   | 0       |
|                | 2    | CS_ERR     | Checksum Error Flag. Set HIGH when ancillary data packet checksum error has been detected.  | R   | 0       |
| -              | 1    | SAV_ERR    | Start of Active Video Error Flag. Set HIGH when<br>TRS errors are detected in either 8-bit or 10-bit<br>TRS words.  | R   | 0       |
|                | 0    | EAV_ERR    | End of Active Video Error Flag. Set HIGH when<br>TRS errors are detected in either 8-bit or 10-bit<br>TRS words.  | R   | 0       |

## Table 3-11: Host Interface Description for Error Status Register

| Register Name | Bit           | Name                      | Description                                | R/W | Default |
|---------------|---------------|---------------------------|--|-----|---------|
| ERROR_MASK    | 15-7          | _                         | Not Used                                   | _   | _       |
| Address: 25h  | 6             | VD_STD_ERR_MASK           | Video Standard Error Flag Mask bit.        | R/W | 0       |
|               | 5             | FF_CRC_ERR_MASK           | Full Field CRC Error Flag Mask bit.        | R/W | 0       |
|               | 4             | AP_CRC_ERR_MASK           | Active Picture CRC Error Flag Mask bit     | R/W | 0       |
| 3             | LOCK_ERR_MASK | Lock Error Flag Mask bit. | R/W  | 0   |         |
|               | 2             | CS_ERR_MASK               | Checksum Error Flag Mask bit.              | R/W | 0       |
| 1<br>0        | 1             | SAV_ERR_MASK              | Start of Active Video Error Flag Mask bit. | R/W | 0       |
|               | 0             | EAV_ERR_MASK              | End of Active Video Error Flag Mask bit.   | R/W | 0       |

Table 3-12: Host Interface Description for Error Mask Register

### 3.9.7.1 Video Standard Error Detection

If a mismatch between the received SMPTE 352M packets and the calculated video standard occurs, the GS9090A will indicate a video standard error by setting the VD\_STD\_ERR bit of the ERROR\_STATUS register HIGH. The device will detect errors in both version 1 and version 0 352M packets.

### 3.9.7.2 EDH CRC Error Detection

The GS9090A calculates the Full Field (FF) and Active Picture (AP) CRC words according to SMPTE RP165 in support of Error Detection and Handling packets in SD signals.

These calculated CRC values are compared with the received CRC values. If a mismatch is detected, the error is flagged in the AP\_CRC\_ERR and/or FF\_CRC\_ERR bits of the ERROR\_STATUS register. These two flags are shared between fields 1 and 2.

The AP\_CRC\_ERR bit will be set HIGH when an active picture CRC mismatch has been detected in field 1 or 2. The FF\_CRC\_ERR bit will be set HIGH when a full field CRC mismatch has been detected in field 1 or 2.

EDH CRC errors will only be indicated when the device has correctly received EDH packets.

SMPTE RP165 specifies the calculation ranges and scope of EDH data for standard 525 and 625 component digital interfaces. The GS9090A will utilize these standard ranges by default.

If the received video format does not correspond to 525 or 625 digital component video standards as determined by the flywheel pixel and line counters, then one of two schemes for determining the EDH calculation ranges will be employed:

- 1. Ranges will be based on the line and pixel ranges programmed by the host interface; or
- 2. In the absence of user-programmed calculation ranges, ranges will be determined from the received TRS timing information.

The registers available to the host interface for programming EDH calculation ranges include active picture and full field line/pixel start and end positions for both fields. Table 3-13 shows the relevant registers, which default to '0' after a device reset.

If any or all of these register values are zero, then the EDH CRC calculation ranges will be determined from the flywheel generated timing. The first active and full field pixel will always be the first pixel after the SAV TRS code word. The last active and full field pixel will always be the last pixel before the start of the EAV TRS code words.

| Register Name                    | Bit   | Name                   | Description  | R/W | Default |
|----------------------------------|-------|------------------------|--|-----|---------|
| AP_LINE_START_F0                 | 15-11 | _                      | Not Used   | -   | -       |
| Address: 15h                     | 10-0  | AP_LINE_START_F0[10:0] | Field 0 Active Picture start line data<br>used to set EDH calculation range<br>outside of SMPTE RP 165 values. | R/W | 0       |

## Table 3-13: Host Interface Description for EDH Calculation Range Registers (Continued)

### 3.9.7.3 Lock Error Detection

The LOCKED pin of the GS9090A indicates the lock status of the internal reclocker and lock detect blocks of the device. Only when the LOCKED pin is asserted HIGH has the device correctly locked to the received data stream (see Lock Detect on page 23).

The GS9090A will also indicate lock error to the host interface when LOCKED = LOW by setting the LOCK\_ERR bit in the ERROR\_STATUS register HIGH.

### 3.9.7.4 Ancillary Data Checksum Error Detection

The GS9090A will calculate checksums for all received ancillary data and compare the calculated values to the received checksum words. If a mismatch is detected, the CS\_ERR bit of the ERROR\_STATUS register will be set HIGH.

Although the GS9090A will calculate and compare checksum values for all ancillary data types by default, the host interface may program the device to check only certain types of ancillary data checksums. This is accomplished via the ANC\_TYPE registers as described in Programmable Ancillary Data Detection on page 32.

### 3.9.7.5 TRS Error Detection

TRS error flags are generated by the GS9090A when:

- 1. The received TRS H timing does not correspond to the internal flywheel timing; or
- 2. The received TRS hamming codes are incorrect.

Both 8-bit and 10-bit SAV and EAV TRS words are checked for timing and data integrity errors. These are flagged via the SAV\_ERR and/or EAV\_ERR bits of the ERROR\_STATUS register.

NOTE: H timing based TRS errors will only be generated if the FW\_EN pin is set HIGH. F & V timing errors are not detected or corrected.

## **3.9.8 Error Correction and Insertion**

In addition to signal error detection and indication, the GS9090A may also correct certain types of errors by inserting corrected code words, checksums, and TRS values into the data stream. These features are only available in SMPTE mode and the IOPROC\_EN pin must be set HIGH. Individual correction features may be enabled or disabled by setting bits 0 to 3 in the IOPROC\_DISABLE register (Table 3-14).

All of the IOPROC\_DISABLE register bits default to '0' after a device reset, enabling all of the processing features. To disable any individual error correction feature, the host interface must set the corresponding bit HIGH in the IOPROC\_DISABLE register.

| Register Name  | Bit   | Name           | Description  | R/W | Default |
|----------------|-------|----------------|--|-----|---------|
| IOPROC_DISABLE | 15-10 | -              | Not Used   | -   | _       |
| Address: 00h   | 9     | ANC_PKT_EXT    | Ancillary Packet Extraction. When the FIFO is<br>configured for Ancillary Data Extraction mode, the<br>bit must be set HIGH to begin extraction.<br>NOTE: Setting ANC_PKT_EXT LOW will not<br>automatically disable ancillary data extraction (see<br>Ancillary Data Extraction and Reading on page 52). | R/W | 0       |
|                | 8-7   | FIFO_MODE[1:0] | FIFO Mode: These bits control which mode the internal FIFO is operating in (see Table 3-15)  | R/W | 0       |
|                | 6     | H_CONFIG       | Horizontal sync timing output configuration. Set<br>LOW for active line blanking timing. Set HIGH for H<br>blanking based on the H bit setting of the TRS word.<br>See Figure 3-3 in HVF Timing Signal Generation on<br>page 28.   | R/W | 0       |
|                | 5-4   |                | Not Used.  |     |         |
|                | 3     | ILLEGAL_REMAP  | Illegal Code re-mapping. Correction of illegal code<br>words within the active picture. Set HIGH to disable.<br>The IOPROC_EN pin must be set HIGH.  | R/W | 0       |
|                | 2     | EDH_CRC_INS    | Error Detection & Handling (EDH) Cyclical<br>Redundancy Check (CRC) error correction insertion.<br>Set HIGH to disable. The IOPROC_EN pin must be set<br>HIGH.   | R/W | 0       |
|                | 1     | ANC_CSUM_INS   | Ancillary Data Checksum insertion. Set HIGH to disable. The IOPROC_EN pin must be set HIGH.  | R/W | 0       |
|                | 0     | TRS_INS        | Timing Reference Signal Insertion. The device will<br>correct TRS based errors when set LOW (see TRS<br>Error Correction on page 46). The IOPROC_EN pin<br>must also be HIGH.  | R/W | 0       |
|                |       |                | Set this bit HIGH to disable.  |     |         |

## Table 3-14: Host Interface Description for Internal Processing Disable Register

### 3.9.8.1 Illegal Code Remapping

If the ILLEGAL\_REMAP bit of the IOPROC\_DISABLE register is set LOW, the GS9090A will remap all codes within the active picture between the values 3FCh and 3FFh to 3FBh. All codes within the active picture area between the values 00h and 03h will be re-mapped to 04h.

In addition, 8-bit TRS and ancillary data preambles will be remapped to 10-bit values if this feature is enabled.

### 3.9.8.2 EDH CRC Error Correction

If the EDH\_CRC\_INS bit of the IOPROC\_DISABLE register is set LOW, the GS9090A will generate and insert active picture and full field CRC words into the EDH data packets received by the device.

Additionally, when EDH\_CRC\_INS is LOW, the device will set the active picture and full field CRC 'V' bits HIGH in the EDH packet (see EDH Flag Detection on page 34). The AP\_CRC\_V and FF\_CRC\_V register bits will only report the received EDH validity flags.

EDH CRC calculation ranges are described in EDH CRC Error Detection on page 41.

NOTE: Although the GS9090A will modify and insert EDH CRC words and EDH packet checksums, the device will only update EDH error flags when the EDH\_FLAG\_UPDATE bit is set HIGH (see EDH Flag Detection on page 34).

### 3.9.8.3 Ancillary Data Checksum Error Correction

When ancillary data checksum error correction and insertion is enabled, the GS9090A will generate and insert ancillary data checksums for all ancillary data words by default. Where user specified ancillary data has been programmed into the ANC\_TYPE registers of the host interface (see Programmable Ancillary Data Detection on page 32), only the checksums for the ancillary data programmed will be corrected.

This feature is enabled when the ANC\_CSUM\_INS bit of the IOPROC\_DISABLE register is set LOW.

#### 3.9.8.4 TRS Error Correction

When TRS error correction and insertion is enabled, the GS9090A will generate and insert 10-bit TRS code words as required.

TRS word generation will be performed in accordance with the timing parameters generated by the flywheel to provide an element of noise immunity. As a result, TRS correction will only take place if the flywheel in enabled (FW\_EN = HIGH).

In addition, the TRS\_INS bit of the IOPROC\_DISABLE register must be set LOW.

NOTE: Only H timing based errors will be corrected (see TRS Error Detection on page 44).

## **3.10 Internal FIFO Operation**

The GS9090A contains an internal video line-based FIFO, which can be programmed to work in any of the following modes:

- 1. Video Mode,
- 2. DVB-ASI Mode,
- 3. Ancillary Data Extraction Mode, or
- 4. Bypass Mode

The FIFO can be configured to one of the four modes by using the host interface to set the FIFO\_MODE[1:0] bits of the IOPROC\_DISABLE register (see Table 3-14 in Error Correction and Insertion on page 44). The setting of these bits is shown in Table 3-15. To enable the FIFO, the FIFO\_EN pin must be set HIGH. Additionally, if the FIFO is configured for video mode or ancillary data extraction mode, the IOPROC\_EN pin must be set HIGH.

The FIFO is fully asynchronous, allowing simultaneous read and write access. It has a depth of 2048 words, which will accommodate 1 full line of SD video for both 525 and 625 standards. The FIFO is 15 bits wide: 10 bits for video data and 5 bits for other signals, such as H, V, F, EDH\_DETECT, and ANC\_DETECT.

#### Table 3-15: FIFO Configuration Bit Settings

| FIFO Mode                      | FIFO_MODE[1:0]<br>Register Setting | FIFO_EN<br>Pin Setting | IOPROC_EN<br>Pin Setting |
|--------------------------------|------------------------------------|------------------------|--------------------------|
| Video Mode                     | 00b                                | HIGH                   | HIGH                     |
| DVB-ASI Mode                   | 01b                                | HIGH                   | Х                        |
| Ancillary Data Extraction Mode | 10b                                | HIGH                   | HIGH                     |
| Bypass Mode                    | 11b                                | Х                      | Х                        |

NOTE: 'X' signifies 'don't care'. The pin is ignored and may be set HIGH or LOW.

## 3.10.1 Video Mode

The internal FIFO is in video mode when the FIFO\_EN and IOPROC\_EN pins are set HIGH, and the FIFO\_MODE[1:0] bits in the IOPROC\_DISABLE register are configured to 00b. By default, the FIFO\_MODE[1:0] bits are set to 00b by the device whenever the SMPTE\_BYPASS pin is set HIGH and the DVB\_ASI pin is set LOW (i.e. the device is in SMPTE mode); however, the FIFO\_MODE[1:0] bits may be programmed as required.

Figure 3-6 shows the input and output signals of the FIFO when it is configured for video mode.

Figure 3-6: FIFO in Video Mode

When operating in video mode, the GS9090A will write data sequentially into the FIFO, starting with the first active pixel in location zero of the memory. In this mode, it is possible to use the FIFO for clock phase interchange and data alignment / delay. The extracted H, V, and F information will also be written into the FIFO. The H, V, and F outputs will be timed to the video data read from the FIFO (see HVF Timing Signal Generation on page 28).

The device will ensure write-side synchronization is maintained, according to the extracted PCLK and flywheel timing information.

Full read-control of the FIFO is made available such that data will be clocked out of the FIFO on the rising edge of the externally provided RD\_CLK signal. When there is a HIGH-to-LOW transition at the RD\_RESET pin the first pixel presented to the video data bus will be the first 000 of the SAV (see Figure 3-7). The FIFO\_LD pulse may be used to control the RD\_RESET pin.

NOTE: The RD\_RESET pulse should not be held LOW for more than one RD\_CLK cycle.

Figure 3-7: RD\_RESET Pulse Timing

In video mode, the ANC\_DETECT output signal will be timed to the data output from the FIFO (see Ancillary Data Detection and Indication on page 31 for more detail).

## 3.10.2 DVB-ASI Mode

The internal FIFO is in DVB-ASI mode when the FIFO\_EN pin is set HIGH, and the FIFO\_MODE[1:0] bits in the IOPROC\_DISABLE register are configured to 01b. By default, the FIFO\_MODE[1:0] bits are set to 01b by the device whenever the DVB\_ASI pin is set HIGH (i.e. the device is in DVB-ASI mode); however, the FIFO\_MODE[1:0] bits may be programmed as required.

Figure 3-8 shows the input and output signals of the FIFO when it is configured for DVB-ASI Mode.

Figure 3-8: FIFO in DVB-ASI Mode

When operating in DVB-ASI mode, the GS9090A's FIFO can be used for clock rate interchange operation. The extracted 8-bit MPEG packets will be written into the FIFO at 27MHz based on the SYNCOUT signal from the internal DVB-ASI decoder block. The SYNCOUT and WORDERR bits are also stored in the FIFO (see Status Signal Outputs on page 30).

When SYNCOUT goes HIGH, K28.5 stuffing characters have been detected and no data will be written into the FIFO.

Data is read out of the FIFO using the RD\_CLK pin. In DVB-ASI mode, the RD\_RESET pin is not used.

## 3.10.2.1 Reading From the FIFO

The FIFO contains internal read and write pointers used to designate which spot in the FIFO the MPEG packet will be read from or written to. These internal pointers control the status flags FIFO\_EMPTY and FIFO\_FULL, which are available for output on the multi-function output port pins, if so programmed (see Programmable Multi-Function Outputs on page 57).

In the case where the write pointer is originally ahead of the read pointer, the FIFO\_EMPTY flag will be set HIGH when both pointers arrive at the same address (see block A in Figure 3-11). This flag can be used to determine when to stop reading from the device.

A write and read pointer offset may be programmed in the FIFO\_EMPTY\_OFFSET[9:0] register of the host interface. If an offset value is programmed in this register, the

FIFO\_EMPTY flag will be set HIGH when the read and write pointers of the FIFO are at the same address, and will remain HIGH until the write pointer reaches the programmed offset. Once the pointer offset has been exceeded, the FIFO\_EMPTY flag will go LOW (see block B in Figure 3-11).

In the case where the read pointer is originally ahead of the write pointer, the FIFO\_FULL flag will be set HIGH when both pointers arrive at the same address (see block C in Figure 3-11). This flag can be used to determine when to begin reading from the device.

A read and write pointer offset may also be programmed in the FIFO\_FULL\_OFFSET[9:0] register of the host interface. If an offset value is programmed in this register, the FIFO\_FULL flag will be set HIGH when the read and write pointers of the FIFO are at the same address, and will remain set HIGH until the read pointer reaches the programmed offset. Once the pointer offset has been exceeded, the FIFO\_FULL flag will be cleared (see block D in Figure 3-11).

## Gating the RD\_CLK Using the FIFO\_EMPTY Flag

Using the asynchronous FIFO\_EMPTY flag to gate RD\_CLK requires external clock gating circuity to generate a clean burst clock (see Figure 3-9). An example circuit for this application is shown in Figure 3-10.

Figure 3-11: Reading From the FIFO in DVB-ASI Mode

## 3.10.3 Ancillary Data Extraction Mode

The internal FIFO is ancillary data extraction mode when the FIFO\_EN and IOPROC\_EN pins are set HIGH, and the FIFO\_MODE[1:0] bits in the IOPROC\_DISABLE register are configured to 10b.

Once the FIFO enters ancillary data extraction mode, it takes 2200 PCLKs (82us) to initialize the FIFO before ancillary data extraction can begin.

In this mode, the FIFO is divided into two separate blocks of 1024 words each. This allows ancillary data to be written to one side of the FIFO while reading from the other. Thus, in each half of the FIFO, the GS9090A will write the contents of the packets up to a maximum of 1024 8-bit words.

As described in Programmable Ancillary Data Detection on page 32, up to five specific types of ancillary data to be extracted can be programmed in the ANC\_TYPE registers. If the ANC\_TYPE registers are all set to zero, the device will extract all types of ancillary data.

The entire packet, including the ancillary data flag (ADF), data identification (DID), secondary data identification (SDID), data count (DC), and checksum word will be written into the memory. The device will detect ancillary data packet DID's placed anywhere in the video data stream, including the active picture area.

Additionally, the lines from which the packets are to be extracted from can be programmed into the ANC\_LINE\_A[10:0] and ANC\_LINE\_B[10:0] registers, allowing ancillary data from a maximum of two lines per frame to be extracted. If only one line number register is programmed (with the other set to zero), ancillary data packets will be extracted from one line per frame only. When both registers are set to zero, the device will extract packets from all lines.

The extracted ancillary data is read through the host interface starting at address 02Ch up to 42Bh inclusive (1024 words). This must be done while there is a valid video signal present at the serial input and the device is locked (LOCKED = HIGH).

## 3.10.3.1 Ancillary Data Extraction and Reading

To start ancillary data extraction, the ANC\_PKT\_EXT bit of the IOPROC\_DISABLE register must be set HIGH (see Table 3-14 in Error Correction and Insertion on page 44). Packet extraction will begin in the following frame after this bit has been set HIGH.

NOTE: Ancillary data extraction will not begin until 2200 PCLKs (82us) after the device has entered into ancillary data extraction mode (FIFO\_MODE[1:0] = 10b), regardless of the setting of the ANC\_PKT\_EXT bit.

When the FIFO is configured for ancillary data extraction mode, setting the IOPROC\_EN pin LOW will disable packet extraction. If IOPROC\_EN is LOW, the setting of the ANC\_PKT\_EXT host interface bit will be ignored.

Clearing the ANC\_PKT\_EXT bit will not automatically disable ancillary data extraction. To disable ancillary data extraction, switch the FIFO into bypass mode by setting FIFO\_MODE[1:0] = 11b. 2200 PCLK cycles after the device re-enters ancillary data extraction mode, data extraction will commence immediately if ANC\_PKT\_EXT is still HIGH.

The ANC\_DETECT output flag available on the I/O output pin (see Programmable Multi-Function Outputs on page 57) can be used to determine the length of the ancillary data extracted and when to begin reading the extracted data from memory. Recall that ANC\_DETECT is HIGH whenever ancillary data has been detected.

In addition, the data count (DC) word, which is located three words after the ancillary data flag (ADF) in the memory, can be read to determine how many valid user data words (UDW) are present in the extracted packet (see SMPTE 291M for more details). The DC value can then be used to preset how many address reads must be performed to obtain only the user data words.

Ancillary data will be written into the first half of the FIFO until it is full or until the ANC\_DATA\_SWITCH bit is toggled (i.e. a HIGH-to-LOW or LOW-to-HIGH transition). If the ANC\_DATA\_SWITCH bit is not toggled, extracted data will not be written into memory after the first half of the FIFO is full (see block A in Figure 3-12).

When the ANC\_DATA\_SWITCH bit is toggled, new extracted data will be written to the second half starting at address zero (see block B in Figure 3-12). The data in the first half of the FIFO may still be read.

Once the data in the first half of the FIFO has been read, the ANC\_DATA\_SWITCH may be toggled again to enable the second half of the FIFO to be read. The first half of the FIFO will be cleared, and the device will continue to write ancillary data to the second half of the FIFO (see block C in Figure 3-12).

If the ANC\_DATA\_SWITCH bit is toggled again, new extracted data will be written to the first half starting at address zero (see block D in Figure 3-12). The data in the second half of the FIFO may still be read.

Toggling ANC\_DATA\_SWITCH again will clear the second half of the FIFO and restore the read and write pointers to the situation shown in block A. The switching process (shown in blocks A to D in Figure 3-12) will continue with each toggle of the ANC\_DATA\_SWITCH bit.

NOTE: At least 1100 PCLK cycles (41us) must pass between toggles of the ANC\_DATA\_SWITCH bit. The ANC\_DATA\_SWITCH bit must be toggled at a point in the video where no extraction is occurring (i.e. the ANC\_DETECT signal is LOW).

NOTE: At least 1100 PCLK cycles must pass between toggles of the ANC\_DATA\_SWITCH bit. The bit must be toggled at a point where no extraction is occuring (i.e. the ANC signal is LOW).

Figure 3-12: Ancillary Data Extraction and Reading

### 3.10.3.2 Clearing the ANC Data FIFO

When switching to ANC FIFO mode from any other mode and on power up, the user must follow one of the 2 methods below to ensure that the FIFO is fully cleared.

### **Clearing ANC FIFO Method 1:**

- 1. Enable ANC FIFO mode (write 10b into the FIFO\_MODE register).
- 2. Wait for ANC\_FIFO\_READY bit to be asserted.
- 3. Toggle (LOW-to-HIGH-to-LOW) ANC\_DATA\_SWITCH bit (bit 12 of IO\_CONFIG register) twice.

### **Clearing ANC FIFO Method 2:**

- 1. Power on device.
- 2. Set FIFO\_EN pin HIGH.
- 3. Enable ANC FIFO mode (write 10b into the FIFO\_MODE register).
- 4. Set FIFO\_EN pin LOW.
- 5. Set FIFO\_EN pin HIGH.

## 3.10.4 Bypass Mode

The internal FIFO is in bypass mode when the FIFO\_EN or IOPROC\_EN pin is set LOW, or the FIFO\_MODE[1:0] bits in the IOPROC\_DISABLE register are configured to 11b. By default, the FIFO\_MODE[1:0] bits are set to 11b by the device whenever both the SMPTE\_BYPASS and DVB\_ASI pins are LOW; however, the FIFO\_MODE[1:0] bits may be programmed as required.

In bypass mode, the FIFO is not inserted into the video path and data is presented to the output of the device synchronously with the PCLK output. The FIFO will be disabled and placed in static mode to save power.

## **3.11 Parallel Data Outputs**

Data outputs are valid on the rising edge of PCLK as shown in Figure 3-13.

## Figure 3-13: PCLK to Data & Control Signal Output Timing

The data is presented in 10-bit format and may be scrambled or unscrambled, framed or unframed.

The output data format is defined by the settings of the external <u>SMPTE\_BYPASS</u> and DVB\_ASI pins (see <u>Table 3-16</u>). Recall that in Manual mode, these pins are set as inputs to the device. In Auto mode, however, the GS9090A sets the <u>SMPTE\_BYPASS</u> pin as an output status signal.

|                       |               |              | Pin Settings |
|-----------------------|---------------|--------------|--------------|
| Output Data Format    | DOUT[9:0]     | SMPTE_BYPASS | DVB_ASI      |
| 10-bit Data           | DATA          | LOW          | LOW          |
| 10-bit Multiplexed SD | Luma / Chroma | HIGH         | LOW          |
| 10-bit DVB-ASI        | DVB-ASI data  | LOW          | HIGH         |

## Table 3-16: Parallel Data Output Format

## 3.11.1 Parallel Data Bus

The parallel data outputs of the GS9090A support both LVTTL and LVCMOS levels. These outputs use either +1.8V or +3.3V, supplied at the IO\_VDD and IO\_GND pins. When interfacing with +5V logic levels, the IO\_VDD pins should be supplied with +3.3V. For a low power connection, the IO\_VDD pins may be connected to +1.8V.

All outputs, including the PCLK output, will be driven to a high-impedance state if the RESET signal is asserted LOW with the exception of the STAT pins and the DATA\_ERROR pin which will maintain the last state they were in for the duration that RESET is asserted.

## 3.11.2 Parallel Output in SMPTE Mode

When the device is operating in SMPTE mode (see SMPTE Functionality on page 26), SD data is presented to the output bus in multiplexed format. The data will be output on the DOUT[9:0] pins and word aligned according to TRS ID words.

## 3.11.3 Parallel Output in DVB-ASI Mode

When operating in DVB-ASI mode (see DVB-ASI Functionality on page 29), the extracted 8-bit data words will be presented on DOUT[7:0] such that DOUT7 = HOUT is the most significant bit of the decoded transport stream data and DOUT0 = AOUT is the least significant bit.

In addition, DOUT9 and DOUT8 will be configured as the DVB-ASI status signals WORDERR and SYNCOUT respectively. See Status Signal Outputs on page 30 for a description of these DVB-ASI specific output signals.

## 3.11.4 Parallel Output in Data-Through Mode

When operating in Data-Through mode (see Data-Through functionality on page 30), the GS9090A presents data to the output data bus without performing any decoding, descrambling, or word-alignment.

As described in Data-Through functionality on page 30, the data bus outputs will be forced to logic LOW if the device is set to operate in Auto mode but cannot identify SMPTE TRS ID words in the input data stream.

## 3.12 Programmable Multi-Function Outputs

The GS9090A has a multi-function output port that uses 4 pins, STAT0 through STAT3. Each pin can be programmed via the host interface to output one of the following signals: H, V, F, FIFO\_LD, ANC\_DETECT, EDH\_DETECT, FIFO\_FULL, and FIFO\_EMPTY.

| Output Status Signal | Reference  |
|----------------------|--|
| Н                    | HVF Timing Signal Generation on page 28            |
| V                    | HVF Timing Signal Generation on page 28            |
| F                    | HVF Timing Signal Generation on page 28            |
| FIFO_LD              | FIFO Load Pulse on page 30                         |
| ANC_DETECT           | Ancillary Data Detection and Indication on page 31 |
| EDH_DETECT           | EDH Packet Detection on page 33                    |
| FIFO_FULL            | Reading From the FIFO on page 49                   |
| FIFO_EMPTY           | Reading From the FIFO on page 49                   |

Table 3-17: Output Signals Available on Multi-Function Output Ports

The registers that determine the signals present on the STAT [3:0] pins are labelled STAT0\_CONFIG[2:0], STAT1\_CONFIG[2:0], STAT2\_CONFIG[2:0], and STAT3\_CONFIG[2:0] respectively. Table 3-18 shows the setting of the IO\_CONFIG registers for each of the available output signals.

#### Table 3-18: IO\_CONFIG Settings

| Function   | I/O    | IO_CONFIG Setting |
|------------|--------|-------------------|
| Н          | Output | 000b              |
| V          | Output | 001b              |
| F          | Output | 010b              |
| FIFO_LD    | Output | 011b              |
| ANC_DETECT | Output | 100b              |
| EDH_DETECT | Output | 101b              |
| FIFO_FULL  | Output | 110b              |
| FIFO_EMPTY | Output | 111b              |

The default setting for each IO\_CONFIG register depends on the configuration of the device and the internal FIFO mode selected. This is shown in Table 3-19.

NOTE: Signals not relevant to the particular mode of operation will be ignored and be high-impedance when programmed to be displayed on the STAT[3:0] pins. For example, the FIFO\_FULL and FIFO\_EMPTY flags can only be displayed on the STAT[3:0] pins when the device is in DVB-ASI mode. If the FIFO\_FULL or FIFO\_EMPTY value (110 and 111 respectively) is programmed into the IO\_CONFIG registers when the device is in SMPTE mode, the value will be ignored and the I/O pin will be set to a high impedance state.

#### Table 3-19: STAT [3:0] Output Default Configuration

## **3.13 Low-latency Mode**

When the IOPROC\_EN pin is set LOW, the GS9090A will enter a low-latency mode such that the parallel data will be output with the minimum PCLK latency possible. The FIFO and all processing blocks except the descrambling and word alignment blocks will be bypassed when <u>SMPTE\_BYPASS</u> is HIGH.

Low-latency mode will also be selected when <u>SMPTE\_BYPASS</u> is set LOW, regardless of the setting of the IOPROC\_EN signal (see <u>Table 3-20</u>).

In DVB-ASI mode, the device will have a higher latency than low-latency mode, although this latency will be less than SMPTE mode.

NOTE: When in low-latency mode, the STAT pin output of the ANC packet flag is delayed by 15 PCLK cycles with respect to the parallel video output. The length of the flag matches the length of the ANC packet.

| IOPROC_EN Setting | SMPTE_BYPASS Setting | Latency (PCLK Cycles) |
|-------------------|----------------------|-----------------------|
| LOW               | LOW                  | 9                     |
| HIGH              | LOW                  | 10                    |
| LOW               | HIGH                 | 10                    |
| HIGH              | HIGH                 | 25                    |

#### Table 3-20: Pin Settings in Low-latency Mode

NOTE: Latency applies to parallel processing core only.

When the GS9090A is configured for low-latency mode, the H, V, and F output timing will be TRS based blanking only as shown in Figure 3-14. Active line-based timing is not available and the setting of the H\_CONFIG host interface bit will be ignored.

Figure 3-14: H,V,F Timing In Low-latency Mode

## **3.14 GSPI Host Interface**

The GSPI, or Gennum Serial Peripheral Interface, is a 4-wire interface provided to allow the host to enable additional features of the GS9090A and/or to provide additional status information through configuration registers in the device.

The GSPI comprises a serial data input signal SDIN, serial data output signal SDOUT, an active low chip select  $\overline{CS}$ , and a burst clock SCLK.

Because these pins are shared with the JTAG interface port, an additional control signal pin JTAG/HOST is provided. When JTAG/HOST is LOW, the GSPI interface is enabled.

When operating in GSPI mode, the SCLK, SDIN, and  $\overline{CS}$  signals are provided by the application interface. The SDOUT pin is a non-clocked loop-through of SDIN and may be connected to the SDIN of another device, allowing multiple devices to be connected to the GSPI chain. The interface is illustrated in Figure 3-15.

Figure 3-15: GSPI Application Interface Connection

All read or write access to the GS9090A is initiated and terminated by the host processor. Each access always begins with a 16-bit command word on SDIN indicating the address of the register of interest. This is followed by a 16-bit data word on SDIN in write mode, or a 16-bit data word on SDOUT in read mode.

## 3.14.1 Command Word Description

The command word consists of a 16-bit word transmitted MSB first and contains a read/write bit, an Auto-Increment bit and a 12-bit address. Figure 3-16 shows the command word format and bit configurations.

Command words are clocked into the GS9090A on the rising edge of the serial clock SCLK, which operates in a burst fashion.

When the Auto-Increment bit is set LOW, each command word must be followed by only one data word to ensure proper operation. If the Auto-Increment bit is set HIGH, the following data word will be written into the address specified in the command word, and subsequent data words will be written into incremental addresses from the previous data word. This facilitates multiple address writes without sending a command word for each data word.

Auto-Increment may be used for both read and write access.

## 3.14.2 Data Read and Write Timing

Read and write mode timing for the GSPI interface is shown in Figure 3-18 and Figure 3-19 respectively. The timing parameters are defined in Table 3-21.

When several devices are connected to the GSPI chain, only one  $\overline{CS}$  must be asserted during a read sequence.

During the write sequence, all command and following data words input at the SDIN pin are output at the SDOUT pin as is. Where several devices are connected to the GSPI chain, data can be written simultaneously to all the devices that have  $\overline{CS}$  set LOW.

| Parameter      | Definition  | Specification |
|----------------|---|---------------|
| t <sub>0</sub> | The minimum duration of time chip select, CS, must be LOW before the first SCLK rising edge.  | 1.5 ns        |
| t <sub>1</sub> | The minimum SCLK period.  | 18.5 ns       |
| t <sub>2</sub> | Duty cycle tolerated by SCLK.   | 40% to 60%    |
| t <sub>3</sub> | Minimum input setup time.   | 1.5 ns        |
| t <sub>4</sub> | Write Cycle: the minimum duration of time between<br>the last SCLK command (or data word if the<br>Auto-Increment bit is HIGH) and the first SCLK of the<br>data word.                              | 37.1 ns       |
| t <sub>5</sub> | Read Cycle: the minimum duration of time between<br>the last SCLK command (or data word if the<br>Auto-Increment bit is HIGH) and the first SCLK of the<br>data word.                               | 148.4 ns      |
| t <sub>5</sub> | Read Cycle - FIFO in ANC Extraction Mode: the<br>minimum duration of time between the last SCLK<br>command (or data word if the Auto-Increment bit is<br>HIGH) and the first SCLK of the data word. | 222.6 ns      |

## **3.14.3 Configuration and Status Registers**

Table 3-22 summarizes the GS9090A's internal status and configuration registers.

All of these registers are available to the host via the GSPI and are all individually addressable.

Where status registers contain less than the full 16 bits of information, two or more registers may be combined at a single logical address.

| Address     | Register Name     | Reference  |
|-------------|-------------------|--|
| 00h         | IOPROC_DISABLE    | Error Correction and Insertion on page 44                        |
| 01h         | ERROR_STATUS      | Error Detection and Indication on page 39                        |
| 02h         | EDH_FLAG_IN       | EDH Flag Detection on page 34                                    |
| 03h         | EDH_FLAG_OUT      | EDH Flag Detection on page 34                                    |
| 04h         | DATA_FORMAT       | Video Standard Indication on page 39                             |
| 05h         | IO_CONFIG         | Programmable Multi-Function Outputs on page 57                   |
| 06h         | FIFO_EMPTY_OFFSET | Reading From the FIFO on page 49                                 |
| 07h         | FIFO_FULL_OFFSET  | Reading From the FIFO on page 49                                 |
| 08h - 0Eh   | ANC_TYPE          | Ancillary Data Detection and Indication on page 31               |
| 11h - 14h   | RASTER_STRUCTURE  | Automatic Video Standard and Data Format<br>Detection on page 38 |
| 15h - 24h   | EDH_CALC_RANGES   | EDH CRC Error Detection on page 41                               |
| 25h         | ERROR_MASK        | Error Detection and Indication on page 39                        |
| 28h         | FIFO_LD_POSITION  | Programmable FIFO Load Position on page 31                       |
| 02Ch - 42Bh | INTERNAL FIFO     | Ancillary Data Extraction Mode on page 52                        |

Table 3-22: GS9090A Internal Registers

## **3.15 Reset Operation**

When the  $\overline{\text{RESET}}$  signal on the GS9090A is de-asserted ( $\overline{\text{RESET}}$  = LOW to HIGH) the LOCKED and DATA[9:0] signals are valid after a period of 200ns after the rising edge of the  $\overline{\text{RESET}}$  signal. (See Figure 3-20)

The LOCKED or DATA[9:0] signals should not be sampled during this time.

Figure 3-20: Reset Timing

## 3.16 JTAG Operation

When the JTAG/HOST pin is set HIGH, the host interface port (as described in GSPI Host Interface on page 60) will be configured for JTAG test operation. In this mode, pins 16, 17, 19, and 20 become TMS, TCK, TDO, and TDI respectively. In addition, the RESET pin will operate as the test reset pin, as well as resetting the internal registers.

Boundary scan testing using the JTAG interface will be possible in this mode.

There are two methods in which JTAG can be used on the GS9090A:

- 1. As a stand-alone JTAG interface to be used at in-circuit ATE (Automatic Test Equipment) during PCB assembly; or
- 2. Under control of the host for applications such as system power self tests.

When the JTAG tests are applied by ATE, care must be taken to disable any other devices driving the digital I/O pins. If the tests are to be applied only at ATE, this can be accomplished with tri-state buffers used in conjunction with the JTAG/HOST input signal. This is shown in Figure 3-21.

Alternatively, if the test capabilities are to be used in the system, the host may still control the JTAG/HOST input signal, but some means for tri-stating the host must exist in order to use the interface at ATE. This is represented in Figure 3-22.

Figure 3-22: System JTAG

## 3.17 Device Power Up

The GS9090A has a recommended power supply sequence. To ensure correct power up, power the CORE\_VDD pins before the IO\_VDD pins. In order to initialize all internal operating conditions to their default state the RESET pin must be held LOW for a minimum of  $t_{reset} = 1ms$ . (See Figure 3-23)

Device pins can be driven prior to power up without causing damage.

# **5. Application Information**

## 5.1 Typical Application Circuit (Part A)

NOTE: All resistors in Ohms, capacitors in Farads, and inductors in Henrys, unless otherwise noted.

NOTE: For up-to-date component values and detailed operation of the equalizer, please see the GS9074A data sheet.

## **5.2 Typical Application Circuit (Part B)**

# 6. Package & Ordering Information

## **6.1 Package Dimensions**

NOTES:

- 1. DIMENSIONING AND TOLERANCE IS IN CONFORMANCE TO ASME Y14.5-1994
- ALL DIMENSIONS ARE IN MILLIMETERS \* IN DEGREES
- 2. DIMENSION OF LEAD WIDTH APPLIES TO METALLIZED TERMINAL AND IS MEASURED BETWEEN 0.15mm AND 0.30mm FROM THE TERMINAL TIP (BOTH ROWS). IF THE TERMINAL HAS OPTIONAL RADIUS ON THE END OF THE TERMINAL, THE LEAD WIDTH DIMENSION SHOULD NOT BE MEASURED IN THAT RADIUS AREA

## **6.2 Recommended PCB Footprint**

The Center Pad of the PCB footprint should be connected to the CORE\_GND plane by a minimum of 25 vias.

NOTE: Suggested dimensions only. Final dimensions should conform to customer design rules and process optimizations.

## 6.3 Packaging Data

| Parameter   | Value                |
|---|----------------------|
| Package Type  | 8mm x 8mm 56-pin QFN |
| Package Drawing Reference   | JEDEC M0220          |
| Moisture Sensitivity Level  | 3                    |
| Junction to Case Thermal Resistance, $\theta_{\text{j-c}}$                  | 12.2°C/W             |
| Junction to Air Thermal Resistance, $\theta_{j\text{-}a}$ (at zero airflow) | 25.8°C/W             |
| Psi   | 9.1°C/W              |
| Pb-free and RoHS compliant  | Yes                  |

## **6.4 Solder Reflow Profiles**

The device is manufactured with Matte-Sn terminations and is compatible with both standard eutectic and Pb-free solder reflow profiles. MSL qualification was performed using the maximum Pb-free reflow profile shown in Figure 6-2. The recommended standard eutectic reflow profile is shown in Figure 6-3.

Figure 6-2: Maximum Pb-free Solder Reflow Profile (Preferred)
