ORDERING INFORMATION

See detailed ordering and shipping information in the package dimensions section on page 11 of this data sheet.

Description

The MC100EL1648 is a voltage controlled oscillator amplifier that requires an external parallel tank circuit consisting of the inductor (L) and capacitor (C). A varactor diode may be incorporated into the tank circuit to provide a voltage variable input for the oscillator (VCO). This device may also be used in many other applications requiring a fixed frequency clock.

The MC100EL1648 is ideal in applications requiring a local oscillator, systems that include electronic test equipment, and digital high−speed telecommunications.

The MC100EL1648 is based on the VCO circuit topology of the MC1648. The MC100EL1648 uses advanced bipolar process technology which results in a design which can operate at an extended frequency range.

The ECL output circuitry of the MC100EL1648 is not a traditional open emitter output structure and instead has an on−chip termination emitter resistor, R_E, with a nominal value of 510 Ω. This facilitates direct ac−coupling of the output signal into a transmission line. Because of this output configuration, an external pull−down resistor is not required to provide the output with a dc current path. This output is intended to drive one ECL load (3.0 pF). If the user needs to fanout the signal, an ECL buffer such as the EL16 (EL11, EL14) type Line Receiver/Driver should be used.

Features

- Typical Operating Frequency Up to 1100 MHz
- Low−Power 19 mA at 5.0 Vdc Power Supply
- PECL Mode Operating Range: V_{CC} = 4.2 V to 5.5 V with V_{EE} = 0 V
- NECL Mode Operating Range: V_{CC} = 0 V with V_{EE} = −4.2 V to −5.5 V
- Input Capacitance = 6.0 pF (TYP)
- These are Pb−Free Devices

NOTE: The MC100EL1648 is NOT useable as a crystal oscillator.

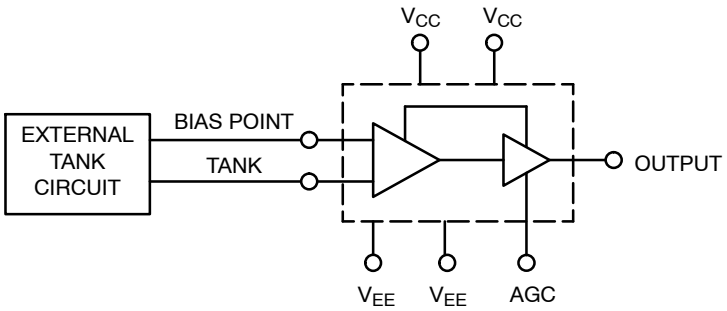

Figure 1. Logic Diagram

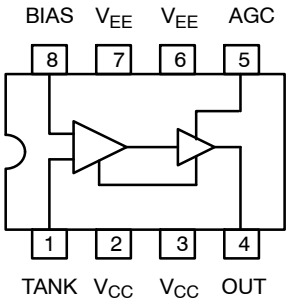
Table 1. PIN DESCRIPTION

Pin No.	Symbol	Description
1	TANK	OSC Input Voltage
2, 3	V_{CC}	Positive Supply
4	OUT	ECL Output
5	AGC	Automatic Gain Control Input
6, 7	V_{EE}	Negative Output
8	BIAS	OSC Input Reference Voltage



Warning: All V_{CC} and V_{EE} pins must be externally connected to Power Supply to guarantee proper operation.

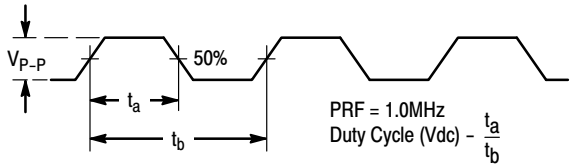

Figure 4. Output Waveform

OPERATION THEORY

Figure 5 illustrates the simplified circuit schematic for the MC100EL1648. The oscillator incorporates positive feedback by coupling the base of transistor Q6 to the collector of Q7. An automatic gain control (AGC) is incorporated to limit the current through the emitter−coupled pair of transistors (Q7 and Q6) and allow optimum frequency response of the oscillator. In order to maintain the high quality factor (Q) on the oscillator, and provide high spectral purity at the output, transistor Q4 is used to translate the oscillator signal to the output differential pair Q2 and Q3. Figure 16 indicates the high spectral purity of the oscillator output (pin 4 on 8−pin SOIC). Transistors Q2 and Q3, in conjunction with output transistor Q1, provide a highly buffered output that produces a square wave. The typical output waveform can be seen in Figure 4. The bias drive for the oscillator and output buffer is provided by Q9 and Q11 transistors. In order to minimize current, the output circuit is realized as an emitter−follower buffer with an on chip pull−down resistor R_E.

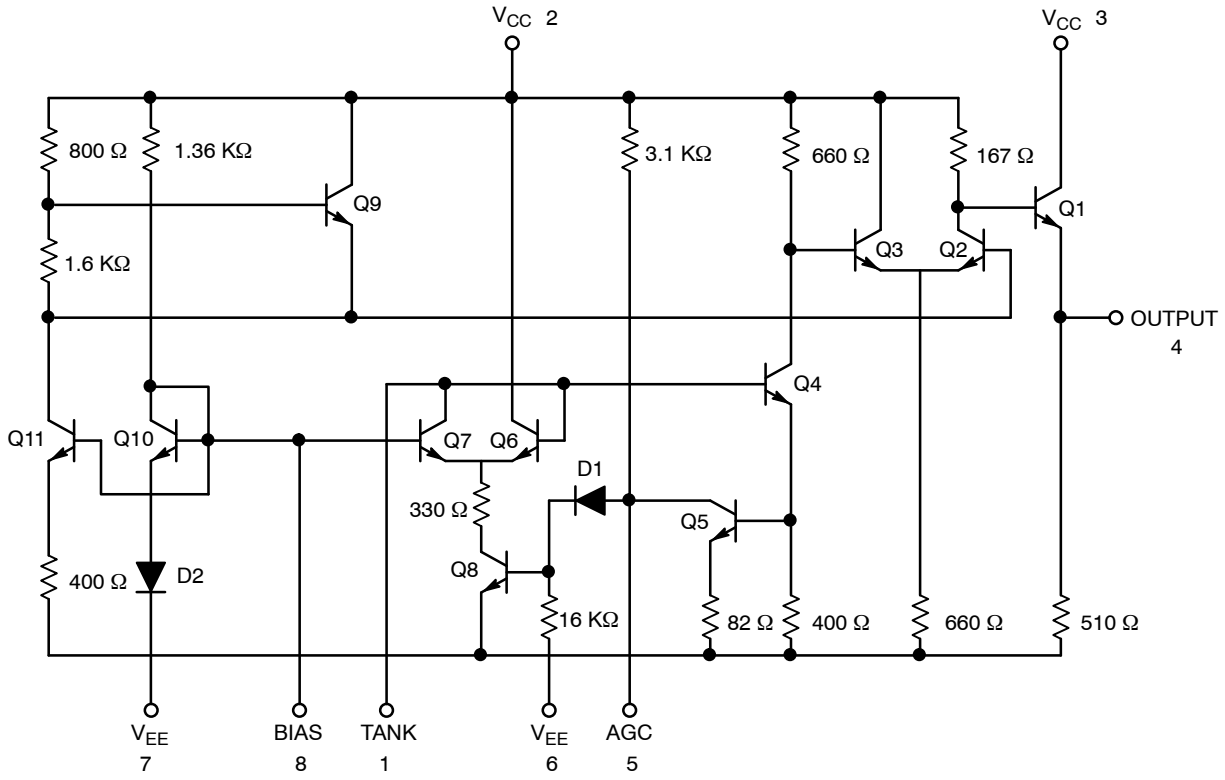

Figure 5. Circuit Schematic

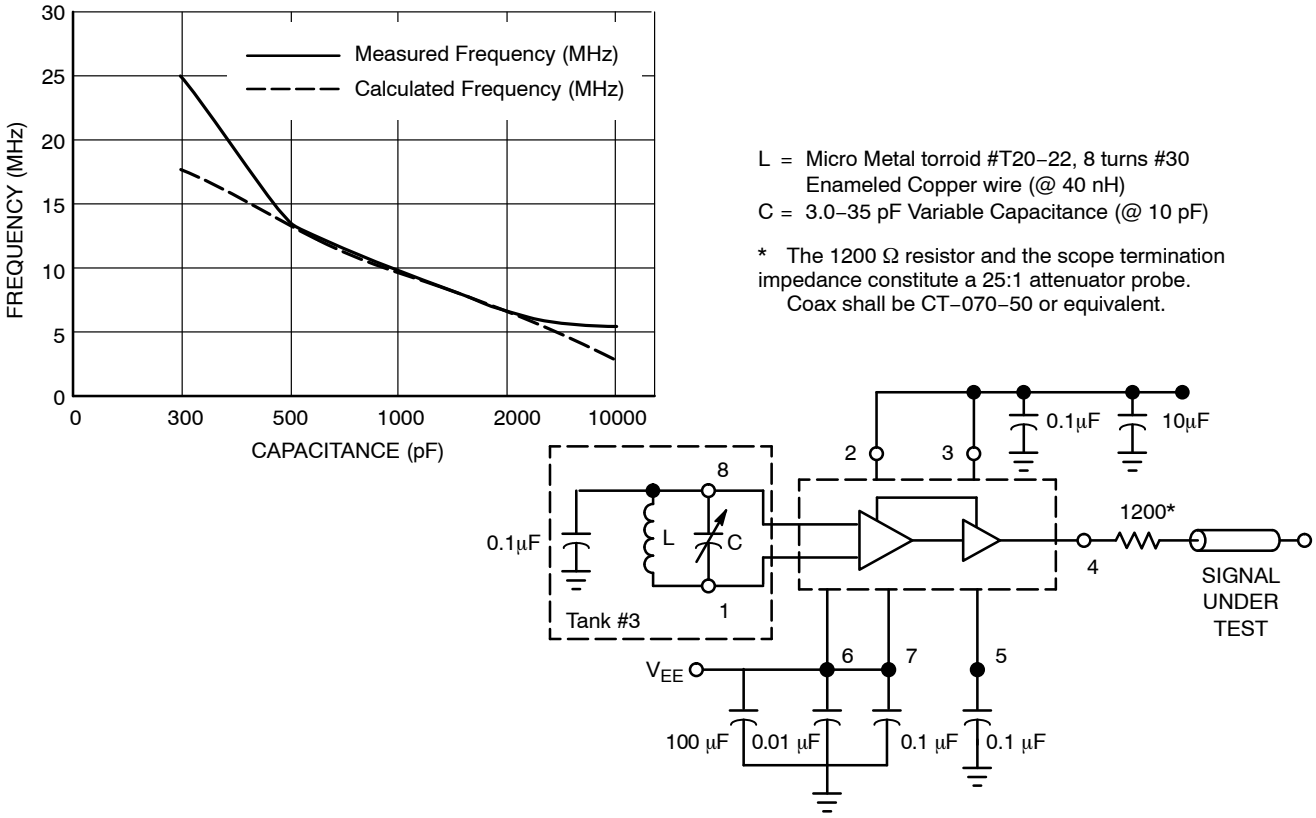

Figure 6. Low Frequency Plot

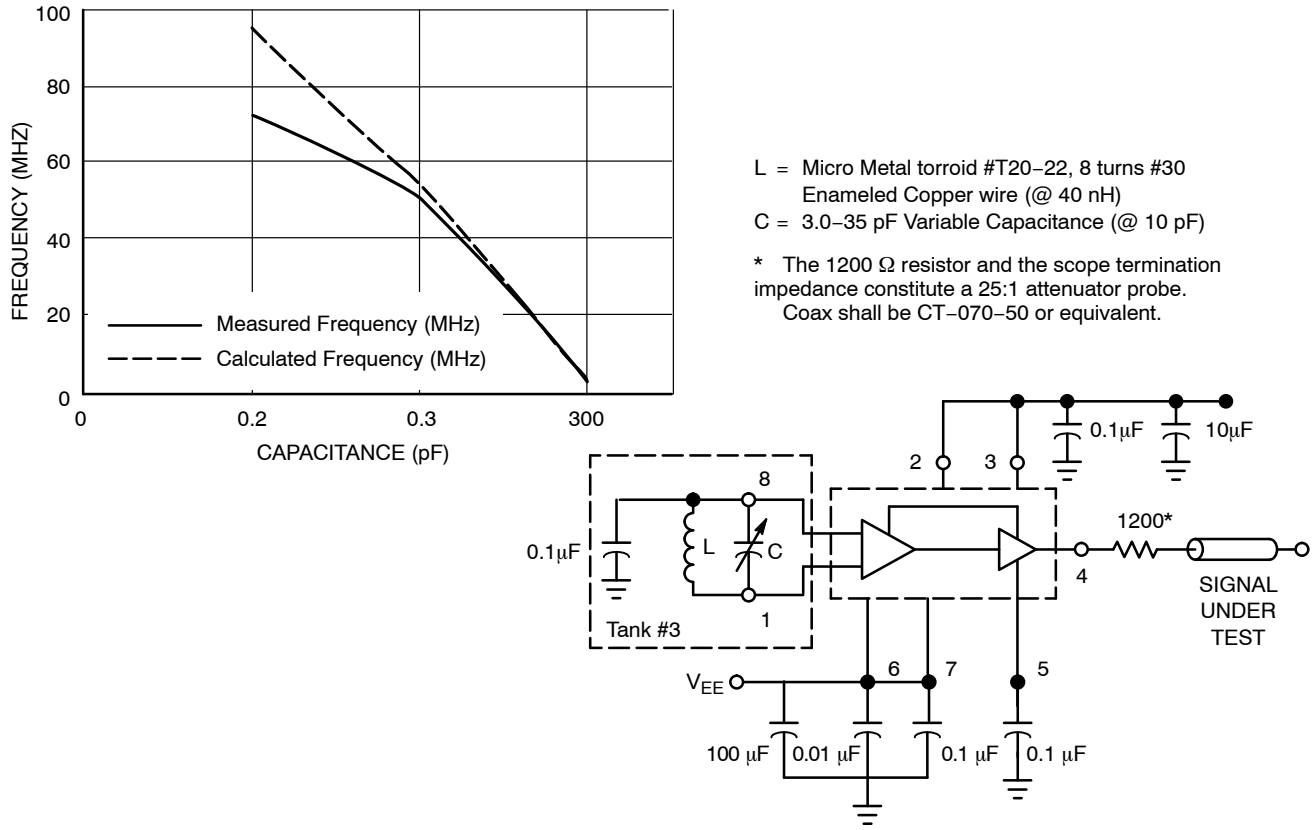

Figure 7. High Frequency Plot

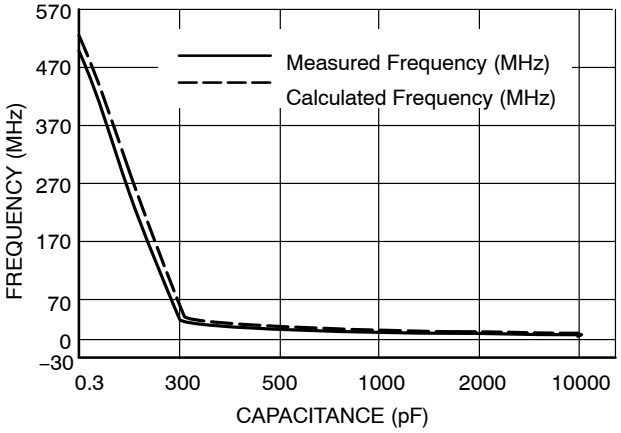
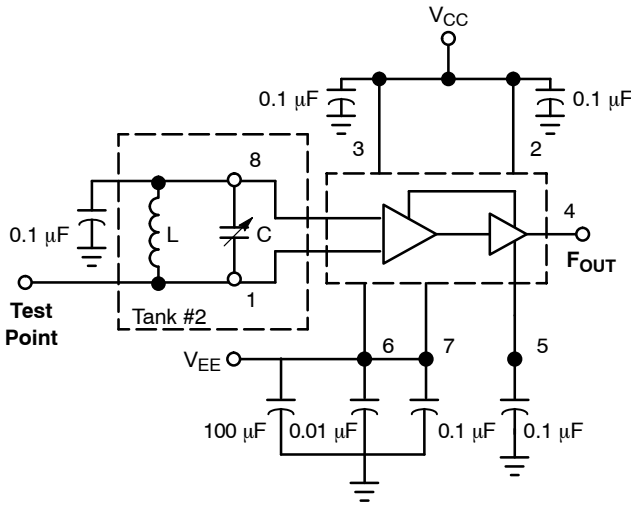
FIXED FREQUENCY MODE

The MC100EL1648 external tank circuit components are used to determine the desired frequency of operation as shown in Figure 8, tank option #2. The tank circuit components have direct impact on the tuning sensitivity, I_{EE}, and phase noise performance. Fixed frequency of the tank circuit is usually realized by an inductor and capacitor (LC network) that contains a high Quality factor (Q). The plotted curve indicates various fixed frequencies obtained with a single inductor and variable capacitor. The Q of the components in the tank circuit has a direct impact on the resulting phase noise of the oscillator. In general, when the Q is high the oscillator will result in lower phase noise.





L = Micro Metal torroid #T20−22, 8 turns #30 Enameled Copper wire (@ 40 nH)
C = 3.0−35 pF Variable Capacitance (@ 10 pF)
Note 1 Capacitor for tank may be variable type. (See Tank Circuit #3.)
Note 2 Use high impedance probe (> 1 MΩ).

$Q_L \geq 100$

Figure 8. Fixed Frequency LC Tank

Only high quality surface−mount RF chip capacitors should be used in the tank circuit at high frequencies. These capacitors should have very low dielectric loss (high−Q). At a minimum, the capacitors selected should be operating at 100 MHz below their series resonance point. As the desired frequency of operation increases, the values of the tank capacitor will decrease since the series resonance point is a function of the capacitance value. Typically, the inductor is realized as a surface−mount chip or a wound coil. In addition, the lead inductance and board inductance and capacitance also have an impact on the final operating point. The following equation will help to choose the appropriate values for your tank circuit design.

$$f_0 = \frac{1}{2\pi \sqrt{L_T * C_T}}$$

Where L_T = Total Inductance
C_T = Total Capacitance

Figure 9 and Figure 10 represent the ideal curve of inductance/capacitance versus frequency with one known tank component. This helps the designer of the tank circuit to choose desired value of inductor/capacitor component for the wanted frequency. The lead inductance and board inductance and capacitance will also have an impact on the tank component values (inductor and capacitor).

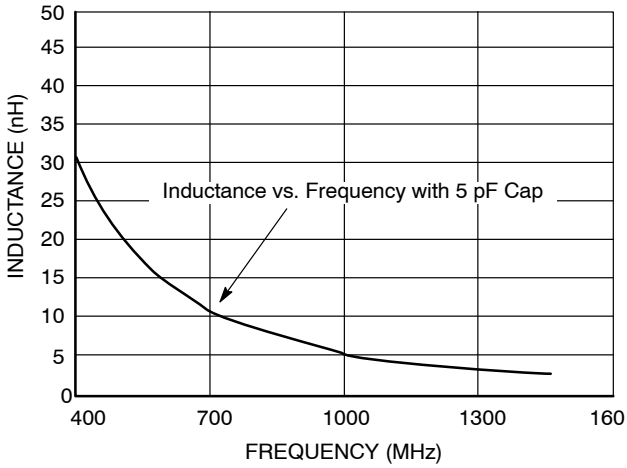


Figure 9. Capacitor Value Known (5 pF)

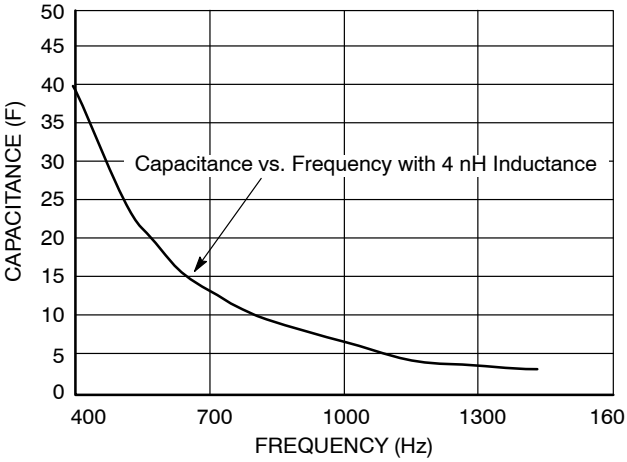

Figure 10. Inductor Value Known (4 nH)

VOLTAGE CONTROLLED MODE

The tank circuit configuration presented in Figure 11, Voltage Controlled Varactor Mode, allows the VCO to be tuned across the full operating voltage of the power supply. Deriving from Figure 6, the tank capacitor, C, is replaced with a varactor diode whose capacitance changes with the voltage applied, thus changing the resonant frequency at which the VCO tank operates as shown in Figure 3, tank option #1. The capacitive component in Equation 1 also needs to include the input capacitance of the device and other circuit and parasitic elements.

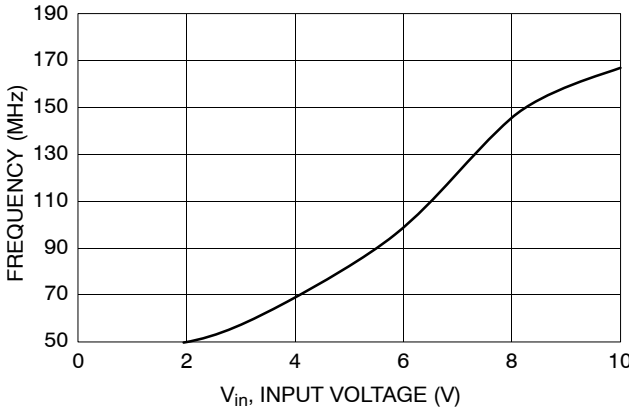

Figure 12. Plot 1. Dual Varactor MMBV609, V_{IN} vs. Frequency

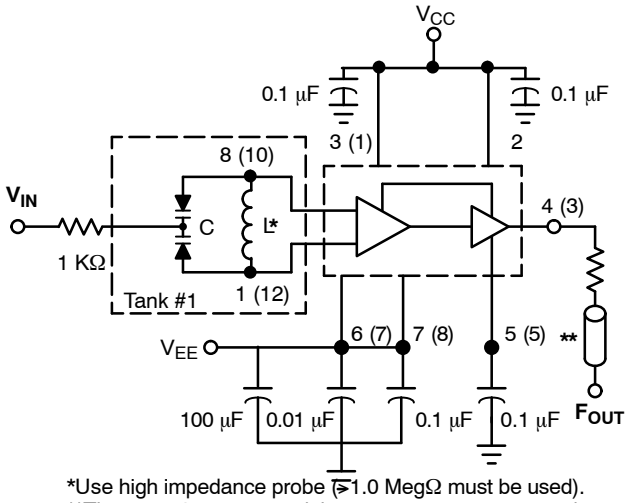

*Use high impedance probe (≥1.0 MegΩ must be used).
**The 1200 Ω resistor and the scope termination impedance constitute a 25:1 attenuator probe. Coax shall be CT−070−50 or equivalent.

L = Micro Metal torroid #T20−22, 8 turns #30 Enameled Copper wire (@ 40 nH)
C = MMBV609

Figure 11. Voltage Controlled Varactor Mode

When operating the oscillator in the voltage controlled mode with Tank Circuit #1 (Figure 3), it should be noted that the cathode of the varactor diode (D), pin 8 (for 8 lead package) or pin 10 (for 14 lead package) should be biased at least 1.4 V above V_{EE}.

Typical transfer characteristics employing the capacitance of the varactor diode (plus the input capacitance of the device, about 6.0 pF typical) in the voltage controlled mode is shown in Plot 1, Dual Varactor MMBV609 V_{in} vs. Frequency. Figure 6, Figure 7, and Figure 8 show the accuracy of the measured frequency with the different variable capacitance values. The 1.0 kΩ resistor in Figure 11 is used to protect the varactor diode during testing. It is not necessary as long as the dc input voltage does not cause the diode to become forward biased. The tuning range of the oscillator in the voltage controlled mode may be calculated as follows:

$$\frac{f_{max}}{f_{min}} = \frac{\sqrt{C_D(max) + C_S}}{\sqrt{C_D(min) + C_S}}$$

Where

$$f_{min} = \frac{1}{2\pi\sqrt{(L(C_D(max) + C_S)}}$$

Where

C_S = Shunt Capacitance (input plus external capacitance)

C_D = Varactor Capacitance as a function of bias voltage

Good RF and low−frequency bypassing is necessary on the device power supply pins. Capacitors on the AGC pin and the input varactor trace should be used to bypass the AGC point and the VCO input (varactor diode), guaranteeing only dc levels at these points. For output frequency operation between 1.0 MHz and 50 MHz, a 0.1 μF capacitor is sufficient. At higher frequencies, smaller values of capacitance should be used; at lower frequencies, larger values of capacitance. At high frequencies, the value of bypass capacitors depends directly on the physical layout of the system. All bypassing should be as close to the package pins as possible to minimize unwanted lead inductance. Several different capacitors may be needed to bypass various frequencies.

WAVE−FORM CONDITIONING − SINE OR SQUARE WAVE

The peak−to−peak swing of the tank circuit is set internally by the AGC pin. Since the voltage swing of the tank circuit provides the drive for the output buffer, the AGC potential directly affects the output waveform. If it is desired to have a sine wave at the output of the MC100EL1648, a series resistor is tied from the AGC point to the most negative power potential (ground if positive volt supply is used, −5.2 V if a negative supply is used) as shown in Figure 13. At frequencies above 100 MHz typical, it may be desirable to increase the tank circuit peak−to−peak voltage in order to shape the signal into a more square waveform at the output of the MC100EL1648. This is accomplished by tying a series resistor (1.0 kΩ minimum) from the AGC to the most positive power potential (+5.0 V if a positive volt supply is used, ground if a −5.2 V supply is used). Figure 14 illustrates this principle.
