Figure 2. Three-State Disable and Enable Timing

Output disable time,  $t_{DIS}$ , is measured from the time the output enable control signal reaches 1.5 V to the time when all outputs have ceased driving. This is calculated by measuring the time,  $t_{MEASURED}$ , from the same starting point to when the output voltages have changed by 0.5 V toward +1.5 V. From the tester capacitive loading,  $C_L$ , and the measured current,  $i_L$ , the decay time,  $t_{DECAY}$ , can be approximated to first order by:

$$t_{DECAY} = \frac{C_L \cdot 0.5 V}{i_L}$$

from which

$$t_{DIS} = t_{MEASURED} - t_{DECAY}$$

is calculated. Disable times are longest at the highest specified temperature.

The maximum output enable time, maximum  $t_{ENA}$ , is also measured from output enable control signal at 1.5 V to the time when all outputs have reached TTL input levels ( $V_{OH}$  or  $V_{OL}$ ). This could also be considered as "data valid." Maximum enable times are longest at the highest specified temperature.
