

MAX9632 Evaluation Kit

Evaluates: MAX9632

General Description

The MAX9632 evaluation kit (EV kit) provides a proven design to evaluate the MAX9632 low-noise, precision and wide-band op amp. The MAX9632 can be used in a wide variety of applications such as test and measurement, instrumentation, medical imaging, control loops, and professional audio. Because of the ultra-low noise and great precision, it can either drive high-resolution (18 to 24 bits) ADCs or buffer high-resolution DACs. The EV kit circuit can easily be adapted by installing shunts and changing a few components to support multiple op-amp configurations: transimpedance, noninverting, inverting, or differential amplifier. The components on the EV kit have pads that accommodate 0805 packages, making them easy to solder and replace. The EV kit accepts a single-supply voltage from +4.5V to +36V or a dual-supply voltage from $\pm 2.25V$ to $\pm 18V$.

Features

- ◆ Accommodates Multiple Op-Amp Configurations
- ◆ +4.5V to +36V Wide Input Supply Range
- ◆ Shutdown Input
- ◆ 0805 Components
- ◆ Proven PCB Layout
- ◆ Fully Assembled and Tested

Ordering Information

PART	TYPE

MAX9632 Evaluation Kit

Evaluates: MAX9632

Quick Start

Required Equipment

- MAX9632 EV kit
- $\pm 15\text{V}$, 40mA DC power supply (PS1)
- +1V precision voltage source
- Digital multimeter (DMM)

Procedure

The EV kit is fully assembled and tested. Follow the steps below to verify board operation:

- 1) Connect the positive terminal of the +15V supply to the VCC pad and the GND terminal to the GND pad. Connect the negative terminal of the -15V supply to the VEE pad and the GND terminal to the GND pad. The power supplies should be off.
- 2) Connect the positive terminal of the precision voltage source to the IN- pad. Connect the negative terminal of the precision voltage source to the IN+ pad.
- 3) Install a shunt on jumper JU2 to short IN+ to GND.
- 4) With the 100Ω feedback resistor and on-board 100Ω resistor, the gain is -1 (inverting configuration).
- 5) Connect the DMM to monitor the voltage on the OUT pad.
- 6) Turn on the $\pm 15\text{V}$ power supply.
- 7) Apply 1V from the precision voltage source. Observe the output at the OUT pad on the DMM. OUT should read approximately -1V.

Detailed Description of Hardware

The MAX9632 EV kit provides a proven layout for the MAX9632 low-noise op amp to support multiple op-amp configurations. The device accepts a single-supply voltage from +4.5V to +36V, or a dual-supply voltage from $\pm 2.25\text{V}$ to $\pm 18\text{V}$.

Jumper Selection

Jumpers JU1 and JU2 are provided to allow flexibility in grounding inputs for multiple op-amp configurations. When a shunt is installed on JU1 or JU2, the corresponding input pad is referenced to ground. See Table 1 for JU1 and JU2 configuration. See the *Op-Amp Configuration* section for more information regarding EV kit configuration.

Shutdown Mode (SHDN)

Jumper JU3 controls the shutdown mode (SHDN) of the device. When SHDN is pulled low, the device is enabled. When the SHDN pin is pulled high, the device is disabled. See Table 2 for JU3 configuration.

Table 1. JU1/JU2 Jumper Selection

SHUNT POSITION	IN-/IN+ INPUT
Installed	Connected to GND
Not installed*	Signal applied at IN-/IN+ pad

*Default position.

Table 2. JU3 Jumper Selection

SHUNT POSITION	SHDN PIN	EV KIT FUNCTION
1-2	Connected to VCC	Disabled
2-3*	Connected to GND	Enabled

*Default position.

Op-Amp Configuration Transimpedance Application

To configure the EV kit as a transimpedance amplifier (TIA), replace R2 with a 0Ω resistor, install a shunt on jumper JU2, and capacitor C5 remains open. The output voltage of the TIA is the input current multiplied by the feedback resistor:

$$V_{OUT} = - (I_{IN} \times I_{BIAS}) \times R4 \pm V_{OS}$$

where R4 is installed as a 100Ω resistor, I_{IN} is defined as IN current, I_{BIAS} is the input bias current, and V_{OS} is the input offset voltage of the op amp. Use capacitor C6 to stabilize the op amp by rolling off high-frequency gain due to a large cable capacitance.

Inverting Configuration

To configure the EV kit as an inverting amplifier, replace R2 and R4 with the desired 1% gain-setting resistors, install a shunt on jumper JU2, and feed a voltage V_{IN} between the IN- and IN+ pads. Install a shunt on JU2 to ground the IN+ input in this configuration. The output voltage is given by the following equation:

$$V_{OUT} = - \frac{R4}{R2} (V_{IN} + V_{OS})$$

The offset voltage V_{OS} can be either positive or negative.

Noninverting Configuration

To configure the device as a noninverting amplifier, replace R2 and R4 with the desired 1% gain-setting resistors, and feed a voltage V_{IN} between the IN+ and IN- pads. Install a shunt on JU1 to ground the IN- input in this configuration. The output voltage is given by the following equation:

$$V_{OUT} = (1 + \frac{R4}{R2}) (V_{IN} \pm V_{OS})$$

Differential Amplifier

To configure the EV kit as a differential amplifier, replace R1–R4 with appropriate resistors. Make sure $R1 = R4$ and $R2 = R3$. The CMRR of the differential amplifier is determined by the matching of the resistor ratios $R4/R2$ and $R1/R3$:

$$V_{OUT} = \text{Gain}(I_{NP} - I_{NN}), \text{ where Gain} = \frac{R4}{R2} = \frac{R1}{R3}$$

Capacitive Loads

Some applications require driving large capacitive loads. To improve the stability of the amplifier in such cases, replace R5 with a suitable resistor value to improve amplifier phase margin. The R5/C7 filter can also be used as an anti-alias filter or to limit amplifier output noise by reducing its output bandwidth.
