## **Functional Description**

### **OPERATING MODES**

The TP3155 control interface requires an 8-bit serial control word which is compatible with the TP3020/TP3021 and 2910/2911 CODECs. Two bits,  $\overline{X}$  and  $\overline{R}$ , define which of the two groups of frame sync outputs,  $FS_X0$  to  $FS_R3$ , is affected by the control word, and a 6-bit assignment field specifies the selected time slot, from 0 to 31. A frame sync output is active-high for one time slot, which is always 8 cycles of BCLK. A frame may consist of any number of time slots up to 32. If a timeslot is assigned which is beyond the number of time slots in a frame, the FS\_R or FS\_R

Two modes of operation are available. Mode 1 is for systems requiring different time slot assignments for the transmit and receive direction of each channel. Mode 1 is selected by leaving pin 9 (MODE) open-circuit or connecting it to V<sub>CC</sub>. In this case, Pin 13 is the RSYNC input which defines the start of each receive frame, and the four outputs, FS<sub>R</sub>0–FS<sub>R</sub>3, are assigned with respect to RSYNC. The XSYNC input defines the start of each transmit frame and outputs FS<sub>X</sub>0–FS<sub>X</sub>3 are assigned with respect to XSYNC. XSYNC may have any phase relationship with RSYNC. Inputs CH0 and CH1 select the channel, from 0 to 3 (see Table Ia).

Mode 2 provides the option of assigning all 8 frame sync outputs with respect to the XSYNC input. Mode 2 is selected by connecting pin 9 (MODE) to GND. This makes the TP3155 TSAC useful for either an 8-channel undirectional controller or for systems in which the transmit and receive directions of each channel are always assigned to the same time slot as the other, i.e., the FS<sub>X</sub> and FS<sub>R</sub> inputs on the COMBO CODEC/Filter are hard-wired together. In this case, logical selection of the channel to be assigned is made via inputs CH0, CH1 and CH2 (see Table Ib).

#### **POWER-UP INITIALIZATION**

During power-up, all frame sync outputs,  $FS_X0-FS_X3$  and  $FS_R0-FS_R3$ , are inhibited and held low. No outputs will go active until a valid time slot assignment is made.

### LOADING CONTROL DATA

During the loading of control data, the binary code for the selected channel must be set on inputs CH0 and CH1 (and CH2 in mode 2), see Tables Ia and Ib.

Control data is clocked into the  $\mathsf{D}_C$  input on the falling edges of  $\mathsf{CLK}_C$  while  $\overline{\mathsf{CS}}$  is low.

A new time slot assignment is transferred to the selected assignment register on the high going transition of  $\overline{\text{CS}}$ . The new assignment is re-synchronized to the system clock such that the new FS output pulses will start at the next complete valid time slot after the rising edge of  $\overline{\text{CS}}$ .

### TIME SLOT COUNTER OPERATION

At the start of TS0 of each transmit frame, defined by the first falling edge of BCLK after XSYNC goes high, the transmit time slot counter is reset to 000000 and begins to increment once every 8 cycles of BCLK. Each count is compared with the 4 transmit assignment registers and, on finding a match, a frame sync pulse is generated at that FS<sub>X</sub> output. Similarly, the first falling edge of BCLK after RSYNC goes high defines the start of receive TS0, and outputs FS<sub>R</sub>0–FS<sub>R</sub>3 are generated with respect to TS0 when the receive time slot counter matches the appropriate receive assignment register.

### TS<sub>X</sub> OUTPUT

In mode 1 (separate transmit and receive assignments), this output pulls low whenever any FS<sub>X</sub> output pulse is being generated. In mode 2, this output pulls low whenever any FS<sub>X</sub> or FS<sub>R</sub> output is being generated. At all other times it is open-circuit, allowing the TS<sub>X</sub> outputs of a number of TSACS to be wire-ANDed together with a common pull-up resistor. This signal can be used to control the TRI-STATE® enable input of a line driver to buffer the transmit PCM bus from the CODEC/Filters to the backplane.

conventions apply:		specified relative to xx. The mnemon may optionally be terminated by an
		or L to specify the high going or lo going transition of the output signa
as: $V_L = 0.4V$ , $V_H = 2.4V$ , $t_R < 10$ ns, $t_F < 10$ ns.		Maximum delay times are measure from xx Valid to yy Valid. Minimum d lay times are measured from xx Valid
Period The period of clock signal is designated as $t_{Pxx}$ where xx represents the mnemonic of the clock signal being specified.		yy Invalid. This parameter is tested u der the load conditions specified in th Conditions column of the Timing Spec fications section of this data sheet.

# **Applications Information**

A combination of the TP3155 TSAC and any CODEC/Filter COMBO from the TP3052/3/4/7 or TP3064/7 series will result in data timing as shown in *Figure 1*. Although the FS<sub>x</sub> output pulse goes high before BCLK goes high, the D<sub>x</sub> output of the combo remains in the TRI-STATE mode until both are high. The eight bit period is shortened to prevent a bus clash, just as it is on the TP3020/1 CODECs.

Alternatively, eight full-length bits can be obtained by inverting the BCLK to the combo devices, thereby aligning rising edges of BCLK and  ${\sf FS}_{X/R}.$ 

*Figure 2* shows typical timing for the control data interface. *Figure 3* shows the digital interconnections of a typical line card application.
