### <span id="page-14-0"></span>**8 Detailed Description**

### <span id="page-14-1"></span>**8.1 Overview**

The bq2461x is a stand-alone, integrated Li-ion or Li-polymer battery charger that accommodates USB applications with a minimum input voltage of 4.7 V. It employs a switched-mode synchronous buck PWM controller with constant switching frequency. The device controls external switches to prevent battery discharge back to the input, to connect the adapter to the system, and to connect the battery to the system using 6-V gate drives for better system efficiency. The bq2461x features Dynamic Power Management (DPM) which reduces battery charge current when the input power limit is reached to avoid overloading the AC adapter when supplying current to the system and the battery charger simultaneously. A highly accurate current sense amplifier enables precise measurement of input current from the AC adapter to monitor the overall system power. The input current limit can be configured through the ACSET pin of the device.

The bq2461x has a battery detect scheme that allows it to automatically detect the presence and absence of a battery. When the battery is detected, charging begins in one of three phases (depending upon battery voltage): precharge, constant current (fast charge current regulation), and constant voltage (fast charge voltage regulation). The device will terminate charging when the termination current threshold has been reached and will begin a recharge cycle when the battery voltage has dropped below the recharge threshold ( $V_{RECHG}$ ). Precharge, constant current, and termination current can be configured through the ISET1 and ISET2 pins, allowing for flexibility in battery charging profile. During charging, the integrated fault monitors of the device, such as battery overvoltage protection, battery short detection ( $V_{\text{BATSHT}}$ ), thermal shutdown (internal T<sub>SHUT</sub> and TS pin), safety timer expiration (TTC pin), and input voltage protection  $(V_{ACOV})$ , ensure battery safety.

The bq2461x has three status pins (STAT1, STAT2, and  $\overline{PG}$ ) to indicate the charging status and input voltage (AC adapter) status. These pins can be used to drive LEDs or communicate with a host processor.

**TEXAS INSTRUMENTS** 

### <span id="page-15-0"></span>**8.2 Functional Block Diagram**

#### <span id="page-16-0"></span>**8.3 Feature Description**

#### **8.3.1 Battery Voltage Regulation**

The bq24618 uses a high-accuracy voltage band gap and regulator for the high charging voltage accuracy. The charge voltage is programmed through a resistor divider from the battery to ground, with the midpoint tied to the VFB pin. The voltage at the VFB pin is regulated to 2.1 V, giving the following equation for the regulation voltage:

$$
V_{BAT} = 2.1 V \times \left[1 + \frac{R2}{R1}\right],
$$

where

• R2 is connected from VFB to the battery.

• R1 is connected from VFB to GND. (1)

#### **8.3.2 Battery Current Regulation**

The ISET1 input sets the maximum fast-charging current. Battery charge current is sensed by resistor  $R_{\text{SR}}$ connected between SRP and SRN. The full-scale differential voltage between SRP and SRN is 100 mV. Thus, for a 10-mΩ sense resistor, the maximum charging current is 10 A. The equation for charge current is:

$$
I_{\text{CHARGE}} = \frac{V_{\text{ISET1}}}{20 \times R_{\text{SR}}}
$$
 (2)

 $V_{\text{ISET1}}$ , the input voltage range of ISET1, is from 0 V to 2 V. The SRP and SRN pins are used to sense voltage across R<sub>SR</sub> using the default value of 10 mΩ. However, resistors of other values can also be used. A larger sense resistor gives a larger sense voltage and a higher regulation accuracy, but at the expense of higher conduction loss.

#### **8.3.3 Input Adapter Current Regulation**

The total input from an AC adapter or other DC source is a function of the system supply current and the battery charging current. System current normally fluctuates as portions of the systems are powered up or down. Without DPM, the source must be able to supply the maximum system current and the maximum charger input current simultaneously. By using DPM, the battery charger reduces the charging current when the input current exceeds the input current limit set by ACSET. The current capability of the AC adaptor can be lowered, reducing system cost.

<span id="page-16-1"></span>Similar to sensing battery regulation current, adaptor current is sensed by resistor  $R_{AC}$  connected between ACP and ACN. Its maximum value is set by ACSET using [Equation 3:](#page-16-1)

$$
I_{\text{DPM}} = \frac{V_{\text{ACSET}}}{20 \times R_{\text{AC}}}
$$
 (3)

VACSET, the input voltage range of ACSET, is from 0 V to 2 V. The ACP and ACN pins are used to sense voltage across R<sub>AC</sub> using the default value of 10 mΩ. However, resistors of other values can also be used. A larger sense resistor gives a larger sense voltage and a higher regulation accuracy, but at the expense of higher conduction loss.

#### **8.3.4 Precharge**

On power up, if the battery voltage is below the  $V_{LOW}$  threshold, the bq24618 applies the precharge current to the battery. This feature is intended to revive deeply discharged cells. If the  $V_{LOW}$  threshold is not reached within 30 minutes of initiating precharge, the charger turns off and a FAULT is indicated on the status pins.

<span id="page-16-2"></span>The precharge current is determined by the voltage on the ISET2 pin,  $V_{ISET2}$ , according to [Equation 4.](#page-16-2)

$$
I_{PRECHARGE} = \frac{V_{ISET2}}{100 \times R_{SR}}
$$

(4)

## **Feature Description (continued)**

#### **8.3.5 Charge Termination, Recharge, and Safety Timer**

The bq24618 monitors the charging current during the voltage regulation phase. When  $V_{TTC}$  is valid, termination is detected while the voltage on the VFB pin is higher than the  $V_{\text{RECH}}$  threshold AND the charge current is less than the  $I_{\text{TERM}}$  threshold, as calculated in [Equation 5](#page-17-0):

$$
I_{\text{TERM}} = \frac{V_{\text{ISET2}}}{100 \times R_{\text{SR}}}
$$

<span id="page-17-1"></span><span id="page-17-0"></span>The input voltage of ISET2 is from 0 V to 2 V. The minimum precharge and termination current is clamped to be around 125 mA with default 10-mΩ sensing resistor. As a safety backup, the bq24618 also provides a programmable charge timer. The charge time is programmed by the capacitor connected between the TTC pin and GND, and is given by [Equation 6](#page-17-1)

$$
t_{\text{CHARGE}} = C_{\text{TTC}} \times K_{\text{TTC}}
$$

where

- $C_{\text{TTC}}$  (range from 0.01 µF to 0.11 µF to give 1-h to 10-h safety time) is the capacitor connected from the TTC pin to GND.
- $K_{\text{TTC}}$  is the constant multiplier (5.6 min/nF). (6)

A new charge cycle is initiated and the safety timer is reset when any of the following conditions occurs:

- The battery voltage falls below the recharge threshold.
- A power-on-reset (POR) event occurs.
- CE is toggled.

The TTC pin may be taken LOW to disable termination and to disable the safety timer. If TTC is pulled to VREF, the bq24618 continues to allow termination but disable the safety timer. TTC taken low resets the safety timer. When ACOV, VCCLOWV, and SLEEP mode resume normal, the safety timer is reset.

#### **8.3.6 Power Up**

The bq24618 uses a SLEEP comparator to determine the source of power on the VCC pin, because VCC can be supplied either from the battery or the adapter. If the VCC voltage is greater than the SRN voltage, the bq24618 enables the ACFET and disables BATFET. If all other conditions are met for charging, the bq24618 then attempts to charge the battery (see *[Enable and Disable Charging](#page-17-2)*). If the SRN voltage is greater than VCC, indicating that the battery is the power source, the bq24618 enables the BATFET and enters a low quiescent current (<15-μA) SLEEP mode to minimize current drain from the battery.

If VCC is below the UVLO threshold, the device is disabled, ACFET turns off, and BATFET turns on.

### <span id="page-17-2"></span>**8.3.7 Enable and Disable Charging**

The following conditions must be valid before charge is enabled:

- CE is HIGH.
- The device is not in UVLO and not in VCCLOWV mode.
- The device is not in SLEEP mode.
- The VCC voltage is lower than the AC overvoltage threshold (VCC  $\lt V_{ACOV}$ ).
- 30-ms delay is complete after initial power up.
- The REGN LDO and VREF LDO voltages are at the correct levels.
- Thermal shutdown (TSHUT) is not valid.
- TS fault is not detected.

Any of the following conditions will stop ongoing charging:

- CE is LOW.
- Adapter is removed, causing the device to enter UVLO, VCCLOWV, or SLEEP mode.
- Adapter is over voltage.
- The REGN or VREF LDOs are overloaded.
- TSHUT IC temperature threshold is reached (145°C on rising edge with 15°C hysteresis).

(5)

- TS voltage goes out of range, indicating the battery temperature is too hot or too cold.
- TTC safety timer times out.

#### **8.3.8 System Power Selector**

The bq24618 automatically switches adapter or battery power to the system load. The battery is connected to the system by default during power up or during SLEEP mode. The battery is disconnected from the system, and then the adapter is connected to the system 30 ms after exiting SLEEP. An automatic break-before-make logic prevents shoot-through currents when the selectors switch.

The ACDRV is used to drive a pair of back-to-back P-channel power MOSFETs between the adapter and ACP with sources connected together and to VCC. The FET connected to the adapter prevents reverse discharge from the battery to the adapter when turned off. The P-channel FET with the drain connected to the adapter input provides reverse battery discharge protection when off; and also minimizes system power dissipation with its low  $r_{DS(on)}$ , compared to a Schottky diode. The other P-channel FET connected to ACP separates the battery from the adapter and provides a limited dI/dt when connecting the adapter to the system by controlling the FET turnon time. The BATDRV controls a P-channel power MOSFET placed between BAT and the system.

When an adapter is not detected, the  $\overline{ACDRV}$  is pulled to VCC to keep ACFET off, disconnecting the adapter from system. BATDRV stays at ACN-6V to connect the battery to the system.

Approximately 30 ms after the device comes out of SLEEP mode, the system begins to switch from battery to adapter. The break-before-make logic keeps both ACFET and BATFET off for 10 µs before ACFET turns on. This prevents shoot-through current or any large discharging current from going into the battery. BATDRV is pulled up to ACN and the ACDRV pin is set to VCC-6V by an internal regulator to turn on P-channel ACFET, connecting the adapter to the system.

When the adapter is removed, the system waits until VCC drops back to within 200 mV above SRN to switch from the adapter back to the battery. The break-before-make logic still keeps 10-μs dead time. The ACDRV is pulled up to VCC and the BATDRV pin is set to ACN-6V by an internal regulator to turn on P-channel BATFET, connecting the battery to the system.

Asymmetrical gate drive (fast turnoff and slow turnon) for the ACDRV and BATDRV drivers provides fast turn-off and slow turn-on of the ACFET and BATFET to help the break-before-make logic and to allow a soft-start at turnon of either FET. The soft-start time can be further increased by putting a capacitor from the gate to the source of the P-channel power MOSFETs.

#### **8.3.9 Automatic Internal Soft-Start Charger Current**

The charger automatically soft-starts the charger regulation current every time the charger goes into fast charge to ensure there is no overshoot or stress on the output capacitors or the power converter. The soft-start consists of stepping up the charge regulation current in eight evenly divided steps up to the programmed charge current. Each step lasts around 1.6 ms, for a typical rise time of 12.8 ms. No external components are needed for this function.

#### **8.3.10 Converter Operation**

The synchronous buck PWM converter uses a fixed-frequency voltage mode with a feed-forward control scheme. A type-III compensation network allows using ceramic capacitors at the output of the converter. The compensation input stage is connected internally between the feedback output (FBO) and the error amplifier input (EAI). The feedback compensation stage is connected between the error amplifier input (EAI) and error amplifier output (EAO). The LC output filter is selected to give a resonant frequency of 12 kHz–17 kHz for the bq24618, where the resonant frequency,  $\rm f_o$ , is given by:

$$
f_{\rm o} = \frac{1}{2\pi\sqrt{L_{\rm o}C_{\rm o}}}
$$

(7)

An internal sawtooth ramp is compared to the internal EAO error control signal to vary the duty cycle of the converter. The ramp height is 7% of the input adapter voltage, making it always directly proportional to the input adapter voltage. This cancels out any loop gain variation due to a change in input voltage and simplifies the loop compensation. The ramp is offset by 300 mV in order to allow zero-percent duty cycle when the EAO signal is below the ramp. The EAO signal is also allowed to exceed the sawtooth ramp signal in order to get a 100% duty-

#### **Feature Description (continued)**

cycle PWM request. Internal gate-drive logic allows achieving 99.5% duty cycle while ensuring the N-channel upper device always has enough voltage to stay fully on. If the BTST pin to PH pin voltage falls below 4.2 V for more than three cycles, then the high-side N-channel power MOSFET is turned off and the low-side N-channel power MOSFET is turned on to pull the PH node down and recharge the BTST capacitor. Then the high-side driver returns to 100% duty-cycle operation until the BTST-to-PH voltage is detected to fall low again due to leakage current discharging the BTST capacitor below 4.2 V, and the reset pulse is reissued.

The fixed-frequency oscillator keeps tight control of the switching frequency under all conditions of input voltage, battery voltage, charge current, and temperature, simplifying output filter design and keeping it out of the audible noise region. Also see *[Application and Implementation](#page-26-0)* for selection of the inductor, capacitor, and MOSFET.

#### **8.3.11 Synchronous and Nonsynchronous Operation**

The charger operates in synchronous mode when the SRP-SRN voltage is above 5 mV (0.5-A inductor current for a 10-mΩ sense resistor). During synchronous mode, the internal gate-drive logic ensures there is breakbefore-make complementary switching to prevent shoot-through currents. During the 30-ns dead time where both FETs are off, the body diode of the low-side power MOSFET conducts the inductor current. Having the low-side FET turn on keeps the power dissipation low and allows safely charging at high currents. During synchronous mode, the inductor current is always flowing and the converter operates in Continuous Conduction Mode (CCM), creating a fixed two-pole system.

The charger operates in nonsynchronous mode when the SRP-SRN voltage is below 5 mV (0.5-A inductor current for a 10-mΩ sense resistor). The charger is forced into nonsynchronous mode when battery voltage is lower than 2 V or when the average SRP-SRN voltage is lower than 1.25 mV.

During nonsynchronous operation, the body diode of the low-side MOSFET can conduct the positive inductor current after the high-side N-channel power MOSFET turns off. When the load current decreases and the inductor current drops to zero, the body diode is naturally turned off and the inductor current becomes discontinuous. This mode is called Discontinuous Conduction Mode (DCM). During DCM, the low-side N-channel power MOSFET turns on for around 80 ns when the bootstrap capacitor voltage drops below 4.2 V. Then the low-side power MOSFET turns off and stays off until the beginning of the next cycle, where the high-side power MOSFET is turned on again. The 80-ns low-side MOSFET on-time is required to ensure the bootstrap capacitor is always recharged and able to keep the high-side power MOSFET on during the next cycle. This is important for battery chargers, where unlike regular DC-DC converters, there is a battery load that maintains a voltage and can both source and sink current. The 80-ns low-side pulse pulls the PH node (the connection between high- and low-side MOSFETs) down, allowing the bootstrap capacitor to recharge up to the REGN LDO value. After 80 ns, the low-side MOSFET is kept off to prevent negative inductor current from occurring.

At very low currents during nonsynchronous operation, there may be a small amount of negative inductor current during the 80-ns recharge pulse. The charge should be low enough to be absorbed by the input capacitance. Whenever the converter goes into zero-percent duty cycle, the high-side MOSFET does not turn on, and the lowside MOSFET does not turn on (only 80-ns recharge pulse) either, and there is almost no discharge from the battery.

During the DCM mode, the loop response automatically changes and has a single pole system at which the pole is proportional to the load current, because the converter does not sink current, and only the load provides a current sink. This means at very low currents the loop response is slower, as there is less sinking current available to discharge the output voltage.

#### **8.3.12 Cycle-by-Cycle Charge Undercurrent Protection**

If the SRP-SRN voltage decreases below 5 mV (the charger is also forced into nonsynchronous mode when the average SRP-SRN voltage is lower than 1.25 mV), the low-side FET is turned off for the remainder of the switching cycle to prevent negative inductor current. During DCM, the low-side FET only turns on for around 80 ns when the bootstrap capacitor voltage drops below 4.2 V to provide refresh charge for the bootstrap capacitor. This is important to prevent negative inductor current from causing a boost effect in which the input voltage increases as power is transferred from the battery to the input capacitors and leads to an overvoltage stress on the VCC node, potentially causing damage to the system.

#### **Feature Description (continued)**

#### **8.3.13 Input Overvoltage Protection (ACOV)**

ACOV provides protection to prevent system damage due to high input voltage. Once the adapter voltage reaches the ACOV threshold, charge is disabled and the system is switched to the battery instead of the adapter.

#### **8.3.14 Input Undervoltage Lockout (UVLO)**

The system must have a minimum VCC voltage to allow proper operation. This VCC voltage could come from either the input adapter or the battery, because a conduction path exists from the battery to VCC through the high-side NMOS body diode. When VCC is below the UVLO threshold, all circuits on the IC are disabled, and the gate-drive bias to ACFET and BATFET is disabled.

#### **8.3.15 Battery Overvoltage Protection**

The converter does not allow the high-side FET to turn on until the BAT voltage goes below 102% of the regulation voltage. This allows one-cycle response to an overvoltage condition, such as occurs when the load is removed or the battery is disconnected. An 8-mA current sink from SRP to GND is on only during charge and allows discharging the stored output inductor energy that is transferred to the output capacitors. BATOVP also suspends the safety timer.

#### **8.3.16 Cycle-by-Cycle Charge Overcurrent Protection**

The charger has secondary cycle-to-cycle overcurrent protection. It monitors the charge current, and prevents the current from exceeding 160% of the programmed charge current. The high-side gate drive turns off when the overcurrent is detected, and automatically resumes when the current falls below the overcurrent threshold.

#### **8.3.17 Thermal Shutdown Protection**

The QFN package has low thermal impedance, which provides good thermal conduction from the silicon to the ambient, to keep junction temperature low. As an added level of protection, the charger converter turns off and self-protects whenever the junction temperature exceeds the TSHUT threshold of 145°C. The charger stays off until the junction temperature falls below 130°C; then the charger soft-starts again if all other charge enabling conditions are valid. Thermal shutdown also suspends the safety timer.

#### **8.3.18 Temperature Qualification**

The controller continuously monitors battery temperature by measuring the voltage between the TS pin and GND. A negative temperature coefficient thermistor (NTC) and an external voltage divider typically develop this voltage. The controller compares this voltage against its internal thresholds to determine if charging is allowed. To initiate a charge cycle, the battery temperature must be within the  $V_{\text{LTE}}$  and  $V_{\text{HTF}}$  thresholds. If battery temperature is outside of this range, the controller suspends charge and the safety timer and waits until the battery temperature is within the  $V_{LTF}$  to  $V_{HTF}$  range. During the charge cycle, the battery temperature must be within the  $V_{LTF}$  and  $V_{TCO}$  thresholds. If battery temperature is outside of this range, the controller suspends charge and waits until the battery temperature is within the  $V_{LTF}$  to  $V_{HTF}$  range. The controller suspends charge by turning off the PWM charge FETs. [Figure 14](#page-21-2) summarizes the operation.

**FXAS NSTRUMENTS** 

#### **Feature Description (continued)**

**Figure 14. TS Pin, Thermistor Sense Thresholds**

<span id="page-21-2"></span><span id="page-21-0"></span>Assuming a 103AT NTC thermistor on the battery pack as shown in [Figure 19](#page-26-3), the values of RT1 and RT2 can be determined by using the following equations:

RT2 = 
$$
\frac{V_{VREF} \times RTH_{COLD} \times RTH_{HOT} \times \left(\frac{1}{V_{LTF}} - \frac{1}{V_{TCO}}\right)}{RTH_{HOT} \times \left(\frac{V_{VREF}}{V_{TCO}} - 1\right) - RTH_{COLD} \times \left(\frac{V_{VREF}}{V_{LTF}} - 1\right)}
$$
\nRT1 = 
$$
\frac{\frac{V_{VREF}}{V_{LTF}} - 1}{\frac{1}{RT2} + \frac{1}{RTH_{COLD}}}
$$
\n(9)

For example, 103AT NTC thermistors are used to monitor the battery pack temperature. Selecting  $T_{\text{COLD}} = 0^{\circ}\text{C}$ and T<sub>CUT</sub> <sub>OFF</sub> = 45<sup>o</sup>C gives R<sub>T2</sub> = 430 kΩ and R<sub>T1</sub> = 9.31 kΩ. A small RC filter is suggested to use for systemlevel ESD protection.

**Figure 15. TS Resistor Network**

#### <span id="page-21-1"></span>**8.3.19 Timer Fault Recovery**

The bq24618 provides a recovery method to deal with timer fault conditions. The following summarizes this method:

**Condition 1:** The battery voltage is above the recharge threshold and a time-out fault occurs.

#### **[www.ti.com](http://www.ti.com)** SLUSA55B –OCTOBER 2010–REVISED APRIL 2015

#### **Feature Description (continued)**

**[bq24618](http://www.ti.com/product/bq24618?qgpn=bq24618)**

**Recovery Method:** The timer fault clears when the battery voltage falls below the recharge threshold, and battery detection begins. A POR condition or taking CE low also clears the fault.

**Condition 2:** The battery voltage is below the recharge threshold and a time-out fault occurs.

**Recovery Method:** Under this scenario, the bq24618 applies the I<sub>FAULT</sub> current to the battery. This small current is used to detect a battery-removal condition and remains on as long as the battery voltage stays below the recharge threshold. If the battery voltage goes above the recharge threshold, the bq24618 disables the fault current and executes the recovery method described in Condition 1. A POR condition or taking CE low also clears the fault.

### **8.3.20 PG Output**

The open-drain PG (power-good) output indicates whether the VCC voltage is valid or not. The open-drain FET turns on whenever the bq24618 has a valid VCC input (not in UVLO or ACOV or SLEEP mode). The PG pin can be used to drive an LED or communicate to the host processor.

#### **8.3.21 CE (Charge Enable)**

The CE digital input is used to disable or enable the charge process. A high-level signal on this pin enables charge, provided all the other conditions for charge are met (see *[Enable and Disable Charging](#page-17-2)*). A high-to-low transition on this pin also resets all timers and fault conditions. There is an internal 1-MΩ pulldown resistor on the CE pin, so if CE is floated, the charge does not turn on.

#### **8.3.22 Charge Status Outputs**

The open-drain STAT1 and STAT2 outputs indicate various charger operations as shown in [Table 2.](#page-22-0) These status pins can be used to drive LEDs or communicate with the host processor. OFF indicates that the opendrain transistor is turned off.

<span id="page-22-0"></span>

#### **Table 2. STAT Pin Definition for bq24618**

**NSTRUMENTS** 

**EXAS** 

#### **8.3.23 Battery Detection**

For applications with removable battery packs, the bq24618 provides a battery-absent detection scheme to reliably detect insertion or removal of battery packs.

**Figure 16. Battery-Detection Flow Chart**

Once the device has powered up, an 8-mA discharge current is applied to the SRN terminal. If the battery voltage falls below the LOWV threshold within 1 second, the discharge source is turned off, and the charger is turned on at low charge current (125 mA). If the battery voltage rises above the recharge threshold within 500 ms, there is no battery present and the cycle restarts. If either the 500-ms or 1-second timer times out before its respective threshold is hit, a battery is detected and a charge cycle is initiated.

**Figure 17. Battery-Detect Timing Diagram**

Ensure that the total output capacitance at the battery node is not so large that the discharge current source cannot pull the voltage below the LOWV threshold during the 1-second discharge time. The maximum output capacitance can be calculated as follows:

$$
C_{MAX} = \frac{I_{DISCH} \times I_{DISCH}}{0.5 \times \left[1 + \frac{R_2}{R_1}\right]}
$$

where

- $C_{MAX}$  is the maximum output capacitance.
- $I<sub>DISCH</sub>$  is the discharge current.
- $t_{DISCH}$  is the discharge time.
- $R_2$  and  $R_1$  are the voltage feedback resistors from the battery to the VFB pin.  $(10)$

The 0.5 factor is the difference between the RECHARGE and the LOWV thresholds at the VFB pin.

#### **Example**

For a three-cell Li+ charger, with R2 = 500 kΩ, R1 = 100 kΩ (giving 12.6 V for voltage regulation),  $I_{DISCH}$  = 8 mA,  $t_{DISCH} = 1$  second,

$$
C_{MAX} = \frac{8mA \times 1sec}{0.5 \times \left[1 + \frac{500k}{100k}\right]} = 2.7 mF
$$
\n(11)

Based on these calculations, no more than 2.7 mF should be allowed on the battery node for proper operation of the battery detection circuit.

#### **8.4 Device Functional Modes**

<span id="page-25-0"></span>

### <span id="page-26-0"></span>**9 Application and Implementation**

#### **NOTE**

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

#### <span id="page-26-1"></span>**9.1 Application Information**

The bq24618 battery charger is ideal for high current charging (up to 10 A) and can charge battery packs consisting of single cells or multiple cells in series. The bq24610EVM evaluation module is a complete charge module for evaluating the bq2461x. The application curves were taken using the bq24610EVM. Refer to the EVM user's guide [\(SLUU396](http://www.ti.com/lit/pdf/SLUU396)) for EVM information.

#### <span id="page-26-2"></span>**9.2 Typical Application**

<span id="page-26-3"></span>

**Figure 19. Typical System Schematic**

#### **Typical Application (continued)**

#### **9.2.1 Design Requirements**

<span id="page-27-0"></span>For this design example, use the parameters listed in [Table 3](#page-27-0) as the input parameters.

#### **Table 3. Design Parameters**

#### **9.2.2 Detailed Design Procedure**

#### *9.2.2.1 Inductor Selection*

The bq2461x has 600-kHz switching frequency to allow the use of small inductor and capacitor values. Inductor saturation current should be higher than the charging current ( $I_{CHG}$ ) plus half the ripple current ( $I_{RIPPLE}$ ):

$$
I_{\text{SAT}} \geq I_{\text{CHG}} + (1/2) I_{\text{RIPPLE}}
$$

The inductor ripple current depends on input voltage (V<sub>IN</sub>), duty cycle (D = V<sub>OUT</sub>/V<sub>IN</sub>), switching frequency (f<sub>S</sub>) and inductance (L):

$$
I_{RIPPLE} = \frac{V_{IN} \times D \times (1 - D)}{f_S \times L}
$$
 (13)

The maximum inductor ripple current happens with  $D = 0.5$  or close to 0.5. For example, the battery charging voltage range is from 9 V to 12.6 V for a three-cell battery pack. For 20-V adapter voltage, 10-V battery voltage gives the maximum inductor ripple current. Another example is a four-cell battery, where the battery voltage range is from 12 V to 16.8 V, and 12-V battery voltage gives the maximum inductor ripple current.

Usually inductor ripple is designed in the range of 20% to 40% of maximum charging current as a trade-off between inductor size and efficiency for a practical design.

The bq24618 has cycle-by-cycle charge undercurrent protection (UCP) by monitoring the charge current-sensing resistor to prevent negative inductor current. The typical UCP threshold is 5 mV falling edge, corresponding to 0.5 A falling edge for a 10-mΩ charge current-sensing resistor.

#### *9.2.2.2 Input Capacitor*

The input capacitor should have enough ripple current rating to absorb the input switching ripple current. The worst-case RMS ripple current is half of the charging current when the duty cycle is 0.5. If the converter does not operate at 50% duty cycle, then the worst-case capacitor RMS current  $I_{\text{C}N}$  occurs where the duty cycle is closest to 50% and can be estimated by the following equation:

$$
I_{\text{CIN}} = I_{\text{CHG}} \times \sqrt{D \times (1 - D)}
$$

 $(14)$ 

(12)

A low-ESR ceramic capacitor such as X7R or X5R is preferred for the input decoupling capacitor and should be placed as close as possible to the drain of the high-side MOSFET and source of the low-side MOSFET. The voltage rating of the capacitor must be higher than the normal input voltage level. A 25-V rating or higher capacitor is preferred for 20-V input voltage. A 10-µF to 20-µF capacitor is suggested for typical 3-A to 4-A charging current.

#### *9.2.2.3 Output Capacitor*

The output capacitor also should have enough ripple current rating to absorb output switching ripple current. The output capacitor RMS current  $I_{\text{COUT}}$  is given:

(15)

$$
I_{\text{COUT}} = \frac{I_{\text{RIPPLE}}}{2 \times \sqrt{3}} \approx 0.29 \times I_{\text{RIPPLE}}
$$

The output capacitor voltage ripple can be calculated as follows:

$$
\Delta V_o = \frac{1}{8L C f_s^2} \left( V_{BAT} - \frac{V_{BAT}^2}{V_{IN}} \right)
$$
\n(16)

At certain input/output voltage and switching frequency, the voltage ripple can be reduced by increasing the output filter LC.

The bq24618 has an internal loop compensator. To get good loop stability, the resonant frequency of the output inductor and output capacitor should be designed from 12 kHz to 17 kHz. The preferred ceramic capacitor is 25- V or higher rating, X7R or X5R for 4-cell applications.

#### *9.2.2.4 Power MOSFET Selection*

Two external N-channel MOSFETs are used for a synchronous switching battery charger. The gate drivers are internally integrated into the IC with 6 V of gate drive voltage. MOSFETs of 30-V or higher voltage rating are preferred for 20-V input voltage and 40-V or higher rating MOSFETs are preferred for 20-V to 28-V input voltage.

Figure-of-merit (FOM) is usually used for selecting proper the MOSFET, based on a trade-off between the conduction loss and switching loss. For a top-side MOSFET, FOM is defined as the product of a MOSFET ONresistance,  $r_{DS(on)}$ , and the gate-to-drain charge,  $Q_{GD}$ . For a bottom-side MOSFET, FOM is defined as the product of the MOSFET ON-resistance,  $r_{DS(on)}$ , and the total gate charge,  $Q_G$ .

$$
FOM_{\text{top}} = R_{DS(\text{on})} \times Q_{GD} \qquad FOM_{\text{bottom}} = R_{DS(\text{on})} \times Q_G \tag{17}
$$

The lower the FOM value, the lower the total power loss. Usually, lower  $r_{DS(0n)}$  has higher cost with the same package size.

The top-side MOSFET loss includes conduction loss and switching loss. It is a function of duty cycle (D =  $V_{\text{OUT}}/V_{\text{IN}}$ , charging current (I<sub>CHG</sub>), MOSFET ON-resistance r<sub>DS(on)</sub>), input voltage (V<sub>IN</sub>), switching frequency (f<sub>S</sub>), turnon time  $(t_{on})$  and turnoff time  $(t_{off})$ :

$$
P_{\text{top}} = D \times I_{\text{CHG}}^2 \times R_{\text{DS(on)}} + \frac{1}{2} \times V_{\text{IN}} \times I_{\text{CHG}} \times (t_{\text{on}} + t_{\text{off}}) \times f_{\text{S}}
$$
(18)

The first item represents the conduction loss. Usually MOSFET r<sub>DS(on)</sub> increases by 50% with a 100ºC junction temperature rise. The second term represents the switching loss. The MOSFET turnon and turnoff times are given by:

$$
t_{on} = \frac{Q_{SW}}{I_{on}}, t_{off} = \frac{Q_{SW}}{I_{off}}
$$

where

- $Q_{\text{sw}}$  is the switching charge.
- $I_{on}$  is the turnon gate-drive current.
- $I_{\text{off}}$  is the turnoff gate-drive current. (19)

If the switching charge is not given in the MOSFET data sheet, it can be estimated by gate-to-drain charge ( $Q_{GD}$ ) and gate-to-source charge  $(Q_{GS})$ :

$$
Q_{SW} = Q_{GD} + \frac{1}{2} \times Q_{GS}
$$
 (20)

Total gate drive current can be estimated by the REGN voltage (V<sub>REGN</sub>), MOSFET plateau voltage (V<sub>olt</sub>), total turnon gate resistance  $(R_{on})$ , and turnoff gate resistance  $(R_{off})$  of the gate driver:

$$
I_{on} = \frac{V_{REGN} - V_{\text{plt}}}{R_{on}}, I_{off} = \frac{V_{\text{plt}}}{R_{off}}
$$
(21)

The conduction loss of the bottom-side MOSFET is calculated with the following equation when it operates in synchronous continuous conduction mode:

**NSTRUMENTS** 

(22)

$$
P_{\text{bottom}} = (1 - D) \times I_{\text{CHG}}^2 \times R_{DS(0n)}
$$

If the SRP-SRN voltage decreases below 5 mV (the charger is also forced into nonsynchronous mode when the average SRP-SRN voltage is lower than 1.25 mV), the low-side FET is turned off for the remainder of the switching cycle to prevent negative inductor current.

As a result, all the freewheeling current goes through the body diode of the bottom-side MOSFET. The maximum charging current in nonsynchronous mode can be up to 0.9 A (0.5 A typical) for a 10-mΩ charging current sensing resistor, considering IC tolerance. Choose the bottom-side MOSFET with either an internal Schottky or body diode capable of carrying the maximum nonsynchronous mode charging current.

MOSFET gate driver power loss contributes to the dominant losses on the controller IC when the buck converter is switching. Choosing a MOSFET with a small  $Q_q$  total reduces the IC power loss to avoid thermal shutdown.

 $P_{\text{lCLoss}}$  driver  $= V_{\text{IN}} \cdot Q_{q}$  total  $\cdot f_s$ 

where

 $Q_{q\text{ total}}$  is the total gate charge for both upper and lower MOSFET at 6 V V<sub>REGN</sub>. (23)

#### *9.2.2.5 Input Filter Design*

During adapter hot plug-in, the parasitic inductance and input capacitor from the adapter cable form a secondorder system. The voltage spike at the VCC pin may be beyond the IC maximum voltage rating and damage the IC. The input filter must be carefully designed and tested to prevent an overvoltage event on the VCC pin. The ACP/ACN pin must be placed after the input ACFET in order to avoid overvoltage stress on these pins during hot plug-in.

There are several methods to damping or limiting the overvoltage spike during adapter hot plug-in. An electrolytic capacitor with high ESR as an input capacitor can damp the overvoltage spike well below the IC maximum pin voltage rating. A high current capability TVS Zener diode can also limit the overvoltage level to an IC-safe level. However, these two solutions may not have low cost or small size.

A cost-effective and small-size solution is shown in [Figure 20](#page-29-0). R1 and C1 comprise a damping RC network to damp the hot plug-in oscillation. As a result, the overvoltage spike is limited to a safe level. D1 is used for reverse voltage protection for the VCC pin (it can be the body diode of the input ACFET). C2 is a VCC pin decoupling capacitor, and it should be placed as close as possible to the VCC pin. R2 and C2 form a damping RC network to further protect the IC from high dv/dt and high-voltage spikes. The value of C2 should be less than the value of C1 so R1 can be dominant over the ESR orf C1 to get enough damping effect for hot plug-in. The R1 and R2 packages must be sized to handle the inrush current power loss according to the resistor manufacturer's data sheet. The filter component values always must be verified with the real application, and minor adjustments may be needed to fit in the real application circuit.

**Figure 20. Input Filter**

#### <span id="page-29-0"></span>*9.2.2.6 Inductor, Capacitor, and Sense Resistor Selection Guidelines*

The bq24618 provides internal loop compensation. With this scheme, best stability occurs when the LC resonant frequency,  $f_o$ , is approximately 12 kHz to 17 kHz for the bq24618.

The following table provides a summary of typical LC components for various charge currents:

#### **Table 4. Typical Inductor, Capacitor, and Sense Resistor Values as a Function of Charge Current for bq24618 (600-kHz Switching Frequency)**

#### *9.2.2.7 Component List for Typical System Circuit of [Figure 19](#page-26-3)*

Texas<br>Instruments

#### **9.2.3 Application Curves**

### <span id="page-32-0"></span>**10 Power Supply Recommendations**

For proper operation of bq2461x, VCC must be from 5 V to 28 V (bq24610) or 24 V (bq24617). To begin charging, VCC must be higher than SRN by at least 500 mV (otherwise, the device will be in sleep mode). TI recommends an input voltage of at least 1.5 V to 2 V higher than the battery voltage, taking into consideration the DC losses in the high-side FET (Rdson), inductor (DCR), and input sense resistor (between ACP and ACN), the body diode drop of RBFET between VCC and input power supply, and battery sense resistor (between SRP and SRN). Power limit for the input supply must be greater than the max power required by either the system load or for battery charging (the greater of the two).

### <span id="page-32-1"></span>**11 Layout**

#### <span id="page-32-2"></span>**11.1 Layout Guidelines**

The switching node rise and fall times should be minimized for minimum switching loss. Proper layout of the components to minimize the high-frequency current-path loop (see [Figure 23\)](#page-33-1) is important to prevent electrical and magnetic field radiation and high-frequency resonance problems. The following is a PCB layout priority list for proper layout. Layout of the PCB according to this specific order is essential.

- 1. Place the input capacitor as close as possible to the switching MOSFET supply and ground connections, and use the shortest-possible copper trace connection. These parts should be placed on the same layer of PCB, instead of on different layers using vias to make the connection.
- 2. The IC should be placed close to the switching MOSFET gate terminals to keep the gate-drive signal traces short for a clean MOSFET drive. The IC can be placed on the other side of the PCB from the switching MOSFETs.
- 3. Place the inductor input terminal as close as possible to the switching MOSFET output terminal. Minimize the copper area of this trace to lower electrical and magnetic field radiation, but make the trace wide enough to carry the charging current. Do not use multiple layers in parallel for this connection. Minimize parasitic capacitance from this area to any other trace or plane.
- 4. The charging-current sensing resistor should be placed right next to the inductor output. Route the sense leads connected across the sensing resistor back to the IC in the same layer, close to each other (minimize loop area), and do not route the sense leads through a high-current path (see [Figure 24](#page-33-2) for the Kelvin connection for best current accuracy). Place decoupling capacitors on these traces next to the IC.
- 5. Place the output capacitor next to the sensing resistor output and ground.
- 6. The output capacitor ground connections must be tied to the same copper that connects to the input capacitor ground before connecting to system ground.
- 7. Route the analog ground separately from the power ground and use a single ground connection to tie the charger power ground to the charger analog ground. Just beneath the IC, use the copper pour for analog ground, but avoid the power pins to reduce inductive and capacitive noise coupling. Connect the analog ground to GND. Connect the analog ground and power ground together using the thermal pad as the single ground connection point. Alternatively, use a 0-Ω resistor to tie the analog ground to power ground (the thermal pad should tie to analog ground in this case). A star-connection under the thermal pad is highly recommended.
- 8. It is critical to solder the exposed thermal pad on the back side of the IC package to the PCB ground. Ensure that there are sufficient thermal vias directly under the IC connecting to the ground plane on the other layers.
- 9. Place decoupling capacitors next to the IC pins, and make the trace connection as short as possible.
- 10. All via sizes and numbers must be adequate for a given current path.

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

www.ti.com 10-Dec-2020

## **PACKAGING INFORMATION**

**(1)** The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures. "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

**(3)** MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**(4)** There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

**(5)** Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

**(6)** Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.
