

### **General Description**

The MAX6618 PECI(1.0)-to-I<sup>2</sup>C translator provides an efficient, low-cost solution for PECI(1.0)-to-SMBus/I<sup>2</sup>C protocol conversion. The PECI(1.0)-compliant host reads temperature data directly from up to four PECI(1.0)-enabled CPUs. This translator will only communicate with CPUs that support PECI 1.0.

The I<sup>2</sup>C interface provides an independent serial communication channel to communicate synchronously with peripheral devices in a multiple master or multiple slave system. This interface allows a maximum serial-data rate of 400kbps.

The MAX6618 is designed to operate from a +3.0V to +3.6V supply voltage and ambient temperature range of -20°C to +120°C.

### **Applications**

Servers

Workstations

**Desktop Computers** 

Pin Configuration appears at end of data sheet.

### **Features**

- ♦ 400kbps I<sup>2</sup>C-Compatible, 2-Wire Serial Interface
- ♦ +3V to +3.6V Supply Voltage
- ◆ PECI(1.0)-Compliant Port
- ♦ PECI(1.0)-to-I<sup>2</sup>C Translation
- **♦ Programmable Temperature Offsets**
- ♦ -20°C to +120°C Operating Temperature Range
- ♦ VREF Input Refers Logic Levels to the PECI Supply Voltage
- ♦ Automatic I<sup>2</sup>C Bus Lockup Timeout Reset
- ♦ Lead-Free, 10-Pin µMAX® Package

### **Ordering Information**

| PART         | TEMP RANGE      | PIN-PACKAGE |
|--------------|-----------------|-------------|
| MAX6618AUB+  | -20°C to +120°C | 10 μMAX     |
| MAX6618AUB+T | -20°C to +120°C | 10 μMAX     |

<sup>+</sup>Denotes a lead(Pb)-free/RoHS-compliant package. T = Tape and reel.

### **Typical Application Circuit**

μΜΑΧ is a registered trademark of Maxim Integrated Products.

### **ABSOLUTE MAXIMUM RATINGS**

| (All voltages with respect to GND.) |                                   | Continuous Power Dissipation (T <sub>A</sub> = +70°C)   |                 |
|-------------------------------------|-----------------------------------|---|-----------------|

| AD0, AD1, AD2,                      | 0.3V to (V <sub>CC</sub> + 0.3V)  | Operating Temperature Range                             | -20°C to +120°C |
| SCL, SDA                            | 0.3V to +6V                       | Junction Temperature                                    | +150°C          |
| VREF                                | 0.3V to +4V                       | Storage Temperature Range                               |                 |
| PECI                                | 0.3V to (V <sub>REF</sub> + 0.3V) | Lead Temperature (soldering, 10s)                       | +300°C          |
| DC Current through SDA              | 10mA                              | Soldering Temperature (reflow)                          |                 |

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### **ELECTRICAL CHARACTERISTICS**

(Typical Application Circuit,  $V_{CC} = +3V$  to +3.6V,  $V_{REF} = +0.95V$  to +1.26V,  $T_A = -20^{\circ}C$  to  $+120^{\circ}C$ , unless otherwise noted. Typical values are at  $V_{CC} = +3.3V$ ,  $V_{REF} = +1.0V$ ,  $T_A = +25^{\circ}C$ .) (Note 1)

| Hold Time                                     | tHOLD                    | Time for client to maintain a low idle drive after MAX6618 begins a message (Note 10)   |     |      | 0.5            | x t <sub>BIT-1</sub> |
| Stop Time                                     | tstop                    | A constant low level driven by MAX6618 (Notes 8, 11)  |     | 2    |                | x t <sub>BIT-M</sub> |
| Maximum Dwell Time of the PECI Client         | <sup>t</sup> RESET       | From the end of a ResetDevice command to the next message to which the reset client must be able to respond                         |     |      | 0.4            | ms                   |
| Minimum PECI Low Time<br>Preceding a Message  | tsetup                   | If the prior $t_{B T}$ is not known by MAX6618, the maximum $t_{B T}$ must be assumed and $t_{SETUP} = 1$ ms in this case (Note 12) | 2   |      |                | x t <sub>BIT-X</sub> |

- **Note 1:** All parameters are tested at  $T_A = +25$ °C. Specifications over temperature are guaranteed by design.
- Note 2: Guaranteed by design; not production tested.
- **Note 3:** A master device must provide a hold time of at least 300ns for the SDA signal (referred to V<sub>IL</sub> of the SCL signal) to bridge the undefined region of SCL's falling edge.
- Note 4: C<sub>b</sub> = total capacitance of one bus line in pF. t<sub>R</sub> and t<sub>F</sub> measured between 0.3 x V<sub>CC</sub> and 0.7 x V<sub>CC</sub>.
- Note 5: I<sub>SINK</sub> ≤ 6mA. C<sub>b</sub> = total capacitance of one bus line in pF. t<sub>R</sub> and t<sub>F</sub> measured between 0.3 x V<sub>CC</sub> and 0.7 x V<sub>CC</sub>.
- Note 6: Input filters on the SDA and SCL inputs suppress noise spikes less than 50ns.
- Note 7: The MAX6618 must drive a more restrictive time to allow for quantized sampling errors by a client yet still attain the minimum time less than 500µs. t<sub>BIT</sub> limits apply equally to t<sub>BIT-M</sub>.
- Note 8: The minimum and maximum bit times are relative to t<sub>BIT</sub> defined in the timing negotiation pulse.
- Note 9: Extended trace lengths can appear as additional nodes.
- **Note 10:** The client may deassert its low idle drive prior to the falling edge of the first bit of the message by using the rising edge to detect a message start. However, the time delay must be sufficient to qualify the rising edge as a true message rather than a noise spike.
- **Note 11:** The message stop is defined by two consecutive periods when the bus has no rising edge. Tolerance around this time is based on the t<sub>BIT-M</sub> error budget.
- Note 12: tSETUP is not additive with tSTOP. Rather, these times may overlap.

### Pin Description

| PIN | NAME             | FUNCTION   |
|-----|------------------|--|
| 1   | PECI             | Platform Environment Control Interface (PECI) Serial-Bus Input/Output  |
| 2   | AGND             | Analog Ground  |
| 3   | AD0              | I <sup>2</sup> C Bus Device Address Selection Input A0   |
| 4   | SDA              | I <sup>2</sup> C Bus Data Input/Output   |
| 5   | SCL              | I <sup>2</sup> C Bus Clock Input   |
| 6   | Vcc              | Power Supply. Bypass to GND with a 0.1µF capacitor.  |
| 7   | GND              | Power-Supply Ground  |
| 8   | AD2              | Internally Connected. Not used for I <sup>2</sup> C slave address selection. Must be connected to GND or V <sub>CC</sub> . |
| 9   | AD1              | Internally Connected. Not used for I <sup>2</sup> C slave address selection. Must be connected to GND or V <sub>CC</sub> . |
| 10  | V <sub>REF</sub> | PECI Input Supply Voltage. Bypass V <sub>REF</sub> to AGND with a 0.1µF capacitor.   |

### Block Diagram

### \_Detailed Description

The MAX6618 obtains temperature data from an internal temperature sensor in PECI-compliant hosts. Up to four PECI hosts can be connected to the PECI I/O interface. The MAX6618 handles all the PECI transmissions

and uses a 2-wire, I<sup>2</sup>C-compatible serial interface to communicate with the PECI host.

### **Registers and Commands**

The following is an overview of the I<sup>2</sup>C/SMBus registers/commands supported by the MAX6618.

| ADDRESS | DESCRIPTION   | TRANSACTION TYPE   |
|---------|---|--------------------|
| 00h     | Read socket 0, domain 0 temperature register                      | ReadWord           |
| 01h     | Read socket 0, domain 1 temperature register                      | ReadWord           |
| 02h     | Read socket 1, domain 0 temperature register                      | ReadWord           |
| 03h     | Read socket 1, domain 1 temperature register                      | ReadWord           |
| 04h     | Read socket 2, domain 0 temperature register                      | ReadWord           |
| 05h     | Read socket 2, domain 1 temperature register                      | ReadWord           |
| 06h     | Read socket 3, domain 0 temperature register                      | ReadWord           |
| 07h     | Read socket 3, domain 1 temperature register                      | ReadWord           |
| 08h     | Read maximum temperature for all enabled sockets/domains register | ReadWord           |
| 09h     | Read firmware version register                                    | ReadWord           |
| 0Ah     | Read maximum temperature address                                  | ReadWord           |
| 0Bh     | Read socket and domain that caused alert                          | ReadWord           |
| 0Ch     | Read/write CONFIG0 register                                       | ReadWord/WriteWord |
| 0Dh     | Read/write CONFIG1 register                                       | ReadWord/WriteWord |
| 0Eh     | Read/write CONFIG2 register                                       | ReadWord/WriteWord |
| 0Fh     | Read/write CONFIG3 register                                       | ReadWord/WriteWord |
| 10h     | Read/write alert temperature for socket 0                         | ReadWord/WriteWord |
| 11h     | Read/write alert temperature for socket 1                         | ReadWord/WriteWord |
| 12h     | Read/write alert temperature for socket 2                         | ReadWord/WriteWord |
| 13h     | Read/write alert temperature for socket 3                         | ReadWord/WriteWord |
| 14h     | Request polling   | SendByte           |
| 15h     | Clear alert   | SendByte           |

### Configuration

The MAX6618 has four configuration registers (Table 1). CONFIGO is the main configuration register that enables the PECI sockets, I<sup>2</sup>C bus timeout, PEC, alert activation, and polling delay. CONFIG1 sets the number of retries,

CONFIG2 sets the temperature offset, and CONFIG3 controls the temperature averaging. You can write to the configuration registers to set the configuration or read from the configuration registers to get the current settings.

**Table 1. Configuration Registers** 

| COMMAND BYTE | REGISTER DESCRIPTION | TYPE               | RESULT                   |
|--------------|----------------------|--------------------|--------------------------|
| 0Ch          | CONFIG0 register     | ReadWord/WriteWord | See the CONFIGO section. |
| 0Dh          | CONFIG1 register     | ReadWord/WriteWord | See the CONFIG1 section. |
| 0Eh          | CONFIG2 register     | ReadWord/WriteWord | See the CONFIG2 section. |
| 0Fh          | CONFIG3 register     | ReadWord/WriteWord | See the CONFIG3 section. |

# PECI-to-I<sup>2</sup>C Translator

#### **CONFIGO**

The CONFIGO register holds a bit mask for PECI sockets and domains that are enabled for polling as well as a polling delay (minimum delay between sets of polls) and features enable/disable bits. Table 2 shows the various options for CONFIGO.

### Table 2. CONFIG0 Register

| BIT(S) | DESCRIPTION   | DEFAULT |
|--------|---|---------|
| 15:8   | Polling enable for sockets and domains  | 00h     |
| 15     | 1 = enable socket 3, domain 1   | 0       |
| 14     | 1 = enable socket 3, domain 0   | 0       |
| 13     | 1 = enable socket 2, domain 1   | 0       |
| 12     | 1 = enable socket 2, domain 0   | 0       |
| 11     | 1 = enable socket 1, domain 1   | 0       |
| 10     | 1 = enable socket 1, domain 0   | 0       |
| 9      | 1 = enable socket 0, domain 1   | 0       |
| 8      | 1 = enable socket 0, domain 0   | 0       |
| 7      | 1 = enable I <sup>2</sup> C bus lockup timeout<br>0 = Disable timeout                         | 1       |
| 6      | 1 = alternate data representation<br>0 = 16-bit data representation                           | 0       |
| 5      | 1 = enable I <sup>2</sup> C packet error checksum (PEC) on device return data 0 = Disable PEC | 1       |
| 4      | 1 = mask temperature alerts<br>0 = Activate alerts  | 0       |
| 3      | Reserved, set to 0  | 0       |
| 2:0    | Poll delay, see Table 3   | 5       |

The optional polling delay (bits 2:0) inserts after polling the set of all sockets and domains that are enabled in bits 15:8 with a minimal pause of 2.5ms between PECI reads. After polling all enabled sockets and domains, the device pauses PECI communications for the configured time before starting to poll the set of enabled sockets and domains again. Table 3 shows the various polling delay options.

Table 3. Polling Delay

| POLL DELAY VALUE | DELAY BETWEEN POLLS (ms) |
|------------------|--------------------------|
| 0                | Polling on request only  |
| 1                | 2.5                      |
| 2                | 5                        |
| 3                | 10                       |
| 4                | 50                       |
| 5                | 100 (default)            |
| 6                | 500                      |
| 7                | Reserved                 |

#### CONFIG1

The CONFIG1 register configures the maximum number of retries before aborting a PECI temperature read as well as the originated (suggested) PECI bit time. Table 4 shows the various options for CONFIG1. Software must configure this value as the register default may cause improper operation.

**Table 4. CONFIG1 Register** 

| BIT(S) | DESCRIPTION  | DEFAULT |
|--------|--|---------|
| 15:8   | Originated PECI bit time (before negotiation) 01h: RESERVED 14h0FFh: CONFIG1[15:8] + 1µs Minimum: 14h (= 21µs / 47.62kHz) Maximum: 0FFh (= 256µs / 3.906kHz) | 02h     |
| 7:0    | Maximum number of retries for PECI transactions  | 03h     |

### PECI-to-I<sup>2</sup>C Translator

#### CONFIG2

The CONFIG2 register holds the offset that is added to all temperature return values that are not error codes. The offset is enabled in CONFIG0, bit 6; +95°C is set as 17C0h or 005Fh, depending on the data format. To represent +95°C in 16-bit representation, convert +95°C to binary using two's complement and left-shift six times. The MAX6618 automatically converts the offset value to the equivalent value when the data format is changed. See Table 5 for the default offset and Table 6 for some example values.

### **Table 5. CONFIG2 Register**

| BIT(S) | DESCRIPTION        | DEFAULT |
|--------|--------------------|---------|
| 15:0   | Temperature offset | 0000h   |

# Table 6. Example Offset Values in 16-Bit Temperature Representation

| TEMP (°C) | HEX   | BIN       | IARY      |  |
|-----------|-------|-----------|-----------|--|
| TEMP (°C) | ПЕХ   | RESHI     | RESLO     |  |
| 0         | 0000h | 0000 0000 | 0000 0000 |  |
| +25       | 0640h | 0000 0110 | 0100 0000 |  |
| +50       | 0C80h | 0000 1100 | 1000 0000 |  |
| +75       | 12C0h | 0001 0010 | 1100 0000 |  |
| +95       | 17C0h | 0001 0111 | 1100 0000 |  |

When configured in CONFIG2 and the return code is not an error code (see the *Error Codes* section), the device adds the offset value stored in CONFIG2 to the return value. For example, if the CPU's thermal control circuit activation point is at +95°C, CONFIG2 can be set to +95°C (005Fh or 17C0h) and all return values are converted to absolute temperatures. Note that the thermal control circuit activation point is CPU specific. The offset value is represented in the current data format.

### **CONFIG3**

CONFIG3 register configures the temperature averaging function. See the *Temperature Averaging* section for more information. Table 7 shows the default settings.

### **Table 7. CONFIG3 Register**

| BIT(S) | DESCRIPTION                        | DEFAULT |
|--------|------------------------------------|---------|
| 15:8   | Reserved, set to 0                 | 00h     |
| 7:0    | Averaging shift count, see formula | 00h     |

### **Temperature Representation**

Temperature data is formatted in 16-bit two's complement representing a range from -512°C to +512°C in steps of 1/64°C (Figure 1). Internally, the device always uses the 16-bit data format. The temperature is given in two's complement and left-shifted so that the +1°C bit is bit 6 (Figure 2). Temperatures can be represented externally in alternate data format if fractional readings are not needed. Table 8 shows some examples.

Figure 1. Temperature Measured in 1/64°C Steps

Figure 2. Conversion of Temperature Done in Two's Complement

# Table 8. Example of 16-Bit Representation with No Offset (Activation Point = +95°C)

| TEMP | RELATIVE  | HEX   | BIN       | ARY       |
|------|-----------|-------|-----------|-----------|
| (°C) | TEMP (°C) | ПЕХ   | RESHI     | RESLO     |
| +94  | -1        | FFC0h | 1111 1111 | 1100 0000 |
| +85  | -10       | FD80h | 1111 1101 | 1000 0000 |
| +70  | -25       | FDC0h | 1111 1101 | 1100 0000 |
| +45  | -50       | F380h | 1111 0011 | 1000 0000 |
| +20  | -75       | ED30h | 1110 1101 | 0100 0000 |

# PECI-to-I<sup>2</sup>C Translator

### Alternate Temperature Value Representation

This optional feature can be enabled using bit 6 of CONFIGO. When the alternate data format is enabled, the temperature value is shifted right as shown in Table 9. The most significant bits are set to all 0s or all 1s depending on the sign bit 15, also shown as S in Figure 3. Table 10 shows some example values. This translation is not performed for error codes (16-bit values from 8000h through 81FFh).

Excluding error codes, the software only has to examine the RESLO data byte, as it represents an integer value in the range from -128°C to +127°C in 1°C steps. The RESHI byte is all 0s or all 1s for valid return codes, and either 80h or 81h for all error codes.

# **Table 9. Alternate Temperature Representation**

| DESCRIPTION              | RESHI                 | RESLO               |
|--------------------------|-----------------------|---------------------|
| 16-bit value             | 15:14:13:12:11:10:9:8 | 7:6:5:4:3:2:1:0     |
| Alternate representation | 15:15:15:15:15:15     | 15:12:11:10:9:8:7:6 |

### Temperature Averaging

The MAX6618 can average several temperature readings and return a value as calculated by:

$$T_{NEW} = \frac{1}{2CONFIG3} \times T_{PECI} + \left(1 - \frac{1}{2CONFIG3}\right) \times T_{OLD}$$

where  $T_{OLD}$  is the previously stored temperature,  $T_{PECI}$  is the new value read from PECI, and  $T_{NEW}$  is the newly stored temperature ready to be returned through  $I^2C$ . This calculation can cause significant bits to be lost.

Enable temperature averaging by writing the desired averaging amount to the CONFIG3 register. Writing 00h to the CONFIG3 register disables temperature averaging.

Figure 3. Alternate Temperature Representation

### Table 10. Example of Alternate Representation with No Offset (Activation Point = $+95^{\circ}$ C)

| TEMP (°C) | DELATIVE TEMP (%C) | HEX   | BINARY    |           |  |
|-----------|--------------------|-------|-----------|-----------|--|
|           | RELATIVE TEMP (°C) | nex - | RESHI     | RESLO     |  |
| +94       | -1                 | FFFFh | 1111 1111 | 1111 1111 |  |
| +85       | -10                | FFF6h | 1111 1111 | 1111 0110 |  |
| +70       | -25                | FFE7h | 1111 1111 | 1110 0111 |  |
| +45       | -50                | FFCEh | 1111 1111 | 1100 1110 |  |
| +20       | -75                | FFB5h | 1111 1111 | 1011 0101 |  |

### **Temperature Commands**

Table 11 shows the different commands for selecting one of the PECI hosts or getting the maximum temperature. Read commands are initiated by the MAX6618, and the result returned is a 16-bit word with the least significant bit (LSB) clocked in first for the selected PECI host.

The result consists of RESLO for the 8 LSBs and RESHI for the 8 MSBs, resulting in a 16-bit word. The 16-bit

words are temperature values read from the PECI interface. PECI-enabled Intel microprocessors return temperature data in fractions of 1°C below the thermal-control-circuit activation point, resulting in negative return values that do not represent absolute temperatures. Absolute temperatures can be achieved by setting the temperature offset in CONFIG2.

Table 12 shows example return values for an Intel CPU. Note that the MAX6618 does not interpret the return

**Table 11. Read Temperature** 

| ADDRESS | REGISTER   | TYPE                  | RESULT       |
|---------|--|-----------------------|--------------|
| 00h     | Socket 0, domain 0                                       |                       |              |
| 01h     | Socket 0, domain 1                                       |                       |              |
| 02h     | Socket 1, domain 0                                       |                       |              |
| 03h     | Socket 1, domain 1                                       |                       |              |
| 04h     | Socket 2, domain 0                                       | ReadWord 16-bit words |              |
| 05h     | Socket 2, domain 1                                       | neadword              | 16-bit words |
| 06h     | Socket 3, domain 0                                       |                       |              |
| 07h     | Socket 3, domain 1                                       |                       |              |
| 08h     | Read maximum temperature for all enabled sockets/domains |                       |              |

**Table 12. Return Temperature Values** 

| RELATIVE         | CONFIC  | G2 OFFSET | RESHI:RES | SLO RESULT |

## PECI-to-I<sup>2</sup>C Translator

data (with the exception of error codes) and the relative temperatures are listed for reference only. Table 12 shows the values with 16-bit and alternate word format.

The read maximum temperature command from Table 11 returns the highest temperature that is not an error code from the enabled PECI sockets and domains. This operation works on signed numbers only and does not give information as to what socket the temperature result comes from. To find the socket and domain, use the read maximum temperature address command as shown in Table 13.

# Table 13. Read Maximum Temperature Address

| COMMAND | DESCRIPTION  | TYPE     | RESULT |
|---------|--|----------|--------|
| 0Ah     | Read address of socket/domain with the maximum temperature | ReadWord | 16-bit |

The read maximum temperature address command returns the register that had the highest temperature when read maximum temperature was last called. An error is returned if the read maximum temperature has not been called or when the read maximum temperature itself returns an error.

### Return Value Flow Chart

Figure 4 shows the operations performed on temperature data read through PECI.

Figure 4. Operational Flowchart

#### **Error Codes**

Error codes are represented as 16-bit words in the range 8000h–81FFh as shown in Table 14.

### **Table 14. Error Codes**

| ERROR<br>CODES  | DESCRIPTION  |
|-----------------|--|
| 8000h-<br>80FFh | Refer to Intel PECI specification.   |
| 8100h           | PECI transaction failed for more than the configured number of consecutive retries.  |
| 8101h           | Polling disabled for requested socket/domain.  |
| 8102h           | First poll not yet completed for requested socket/domain (on startup).   |
| 8103h           | Read maximum temperature requested, but no sockets/domains enabled or all enabled sockets/domains have errors; or read maximum temperature address requested, but read maximum temperature was not called. |
| 8104h           | Get alert socket/domain requested, but no alert active.  |

### **Version Information Command**

Table 15 shows the command to read the firmware version.

**Table 15. Firmware Command** 

| COMMAND | DESCRIPTION          | TYPE     | RESULT      |
|---------|----------------------|----------|-------------|
| 09h     | Get firmware version | ReadWord | 16-bit word |

The result is a 16-bit word (low byte transmitted first, high byte second), e.g., 0100h for the MAX6618 firmware version 1.0.

#### Bus Lockout Timeout Reset

If an I<sup>2</sup>C transaction starts and gets locked up for greater than 20ms, the MAX6618 asserts the internal bus lockup reset that restarts itself in the default startup condition.

#### **Serial Interface**

The MAX6618 operates as a slave that sends and receives data through an I<sup>2</sup>C-compatible, 2-wire interface. The interface uses a serial-data line (SDA) and a serial-clock line (SCL) to achieve bidirectional communication between master and slave. A master (typically a microcontroller) initiates all data transfers to and from the MAX6618 and generates the SCL clock that synchronizes the data transfer (Figure 5).

Figure 5. 2-Wire Serial-Interface Timing Details

# PECI-to-I<sup>2</sup>C Translator

The MAX6618 SCL and SDA lines operate as both inputs and open-drain outputs. A pullup resistor is required on SCL and SDA.

Each transmission consists of a START condition sent by a master, followed by the MAX6618 7-bit slave address, plus an R/W bit, one or more data bytes, and finally a STOP condition (Figure 6). To write to a MAX6618 register, a write transmission consists of a START condition, followed by the MAX6618 7-bit slave address plus  $R/\overline{W} = 0$ , a register address byte, one data byte, and finally a STOP condition. To read from a MAX6618 register, a combined write and read transmissions are required. The first write transmission consists of a START condition, followed by the MAX6618 7-bit slave address plus  $R/\overline{W} = 0$ , a register address byte, and finally a STOP condition that sets the register to be read. The second read transmission consists of a START condition, followed by the MAX6618 7-bit slave address plus  $R/\overline{W} = 1$ , one or more data bytes, and

finally a STOP condition that reads the data from the specified register. These write and read transmissions must be joined using a repeated START without a STOP after the write transaction, even though the MAX6618 7-bit slave address needs to be present preceding the  $R/\overline{W}$  bits.

### Start and Stop Conditions

Both SCL and SDA remain high when the interface is not busy. A master signals the beginning of a transmission with a START (S) condition by transitioning SDA from high to low while SCL is high. When the master has finished communicating with the slave, it issues a STOP (P) condition by transitioning SDA from low to high while SCL is high. The bus is then free for another transmission (Figure 6).

Figure 6. Start and Stop Conditions

Figure 7. Bit Transfer

### Data Transfer and Acknowledge

One data bit is transferred during each clock pulse. The data on SDA must remain stable while SCL is high (Figure 7).

The acknowledge bit is a clocked 9th bit that the recipient uses to handshake receipt of each byte of data (Figure 8). Thus, each byte transferred effectively requires 9 bits. The master generates the 9th clock pulse, and the recipient pulls down SDA during the acknowledge clock pulse so that the SDA line is stable low during the high period of the clock pulse. When the master is transmitting to the MAX6618, the MAX6618 generates the acknowledge bit because the MAX6618 is the recipient. When the MAX6618 is transmitting to the master, the master generates the acknowledge bit because the master is the recipient.

### Slave Address

The MAX6618 has a 7-bit long slave address (Figure 9). The 8th bit following the 7-bit slave address is the R/W bit. The R/W bit is low for a write command and high for a read command.

Figure 8. Acknowledge

The first four bits of the MAX6618 slave address (A6:A3) are always 0101. Bits A2:A1 are set during the manufacturing process to 0:1. A0 is selected by the address input AD0. AD0 can be connected to GND or  $V_{\rm CC}$ . The MAX6618 has two possible slave addresses selectable by AD0. Therefore, a maximum of two MAX6618 devices can be controlled independently from the same interface (see the *I*<sup>2</sup>C Address Range section).

### Message Format for Writing to the MAX6618

A write to the MAX6618 consists of the transmission of the MAX6618's slave address with the  $R/\overline{W}$  bit set to zero, followed by at least 1 byte of information. The first byte of information is the command byte. The command byte determines which register of the MAX6618 is to be written to by the next byte or read from during the next read transmission. If a STOP condition is detected after the command byte is received, then the MAX6618 takes no further action beyond setting the register address.

The bytes received after the command byte are data bytes. The data bytes go into the register of the

Figure 9. Slave Address

MAX6618 specified by the command byte. Only the last data byte or word transmitted before a STOP condition is stored by the device (Figure 10).

### Message Format for Reading the MAX6618

The MAX6618 is read using the MAX6618's internally stored command byte as an address pointer the same way the stored command byte is used as an address pointer for a write. The pointer autoincrements after each data byte is read. Thus, a read is initiated by first

#### TYPICAL READ WORD COMMAND

PEC (PACKET ERROR CHECKSUM) ENABLED

| MASTER  | ADDR:7 | W | A | CMD:8   | Α |         |   |       |    |   |
|---------|--------|---|---|---------|---|---------|---|-------|----|---|
| MAX6618 | ADDR:7 | R | А | RESL0:8 | Α | RESHI:8 | Α | PEC:8 | NA | Р |

### PEC (PACKET ERROR CHECKSUM) DISABLED

| MASTER  | ADDR:7 | W | A | CMD:8   | Α |         |    |   |
|---------|--------|---|---|---------|---|---------|----|---|
| MAX6618 | ADDR:7 | R | А | RESLO:8 | Α | RESHI:8 | NA | Р |

#### TYPICAL WRITE WORD COMMAND

COMMAND WITH PEC (PACKET ERROR CHECKSUM)

| MASTER         S         ADDR:7         W         A         CMD:8         A         INLO:8         A         INHI:8         A         PEC:8 | Α | Р |  |
|---|---|---|--|
|---|---|---|--|

#### COMMAND WITHOUT PEC (PACKET ERROR CHECKSUM)

| MASTER | S | ADDR:7 | W | A | CMD:8 | A | INLO:8 | A | INHI:8 | A | Р |
|--------|---|--------|---|---|-------|---|--------|---|--------|---|---|
|--------|---|--------|---|---|-------|---|--------|---|--------|---|---|

THE RESULT CONSISTS OF RESLO FOR THE 8 LEAST SIGNIFICANT BITS (LSBS) AND RESHI FOR THE 8 MOST SIGNIFICANT BITS (MSBS), RESULTING IN A 16-BIT WORD. TEMPERATURE DATA AND ERROR CODES ARE GIVEN AS 16-BIT WORDS.

ADDR:7: 7-BIT ADDRESS FOLLOWED BY A READ (R = 1) OR WRITE (W = 0) BIT TO FORM THE 8-BIT ADDRESS USED IN THE I<sup>2</sup>C/SMBUS PROTOCOL.

P: I<sup>2</sup>C STOP CONDITION. SEE FIGURE 6.

S: I2C START CONDITION. SEE FIGURE 6.

A: ACK. THE PULSE ON THE 9th CLOCK CYCLE TO INDICATE ACKNOWLEDGE TRANSFER. SLAVE PULLS LOW TO GND AND MASTER PULLS TO SLAVE'S VOI.

NA: NOT ACKNOWLEDGE

CMD: COMMAND BYTE

RESLO: LEAST SIGNIFICANT 8-BIT RESULT
RESHI: MOST SIGNIFICANT 8-BIT RESULT

Figure 10. Typical Read/Write Word Command

configuring the MAX6618's command byte by performing a write. The master can now read N consecutive bytes from the MAX6618 with the first data byte being read from the register addressed by the initialized command byte (Figure 10).

### Packet Error Checksum (PEC)

All MAX6618 I $^2$ C packets have an optional packet error checksum (PEC). The PEC is implemented in accordance with the SMBus specification, versions 1.1 and 2. The MAX6618 accepts commands with or without PEC. The PEC for device responses is optional and can be disabled in the CONFIG0 register.

### **Applications Information**

### **Operation with Multiple Masters**

If the MAX6618 is operated on a 2-wire interface with multiple masters, a master reading the MAX6618 should use a repeated START between the write that sets the MAX6618's address pointer, and the read(s) that takes the data from the location(s) (Table 16). This is because it is possible for master 2 to take over the bus after master 1 has set up the MAX6618's address pointer, but before master 1 has read the data. If master 2 subsequently changes the MAX6618's address pointer, master 1's delayed read can be from an unexpected location. The use of multiple masters is not recommended.

### I<sup>2</sup>C Address Range

In addition to the four MSBs (0101), the I<sup>2</sup>C slave address includes bit A0 (set by the address input AD0) and bits A2:A1 (set to 01). See Table 16.

### **Choosing Pullup Resistors**

I<sup>2</sup>C requires pullup resistors to provide a logic-high level to data and clock lines. There are tradeoffs between power dissipation and speed, and a compromise must be made in choosing pullup resistor values. Every device connected to the bus introduces some capacitance even when the device is not in operation. I<sup>2</sup>C specifies a minimum 300ns rise time to go from low to high (30% to 70%) for fast mode, which is defined for a date rate of 400kbps (refer to the I<sup>2</sup>C specifications for details). To meet the rise time requirement, choose pullup resistors so that the rise time t<sub>R</sub> = 0.85Rpullup x CBus < 300ns. For typical

Table 16. MAX6618 Slave Addresses

| A6:A1<br>(FIXED) | A0<br>(SET BY AD0 PIN) | I <sup>2</sup> C ADDRESS BYTE<br>INCLUDING R/W BIT |  |  |
|------------------|------------------------|--|--|--|
| 010101           | 0                      | 54h, 55h   |  |  |
| 010101           | 1                      | 56h, 57h   |  |  |

### **Pin Configuration**
