## 1. Overview

The Industrial SD Card (ISD) of the SQFlash is fully compliant to the specification released by SD Card Association. The Command List supports [Part 1 Physical Layer Specification Ver3.1 Final] definitions. Card Capacity of Non-secure Area, Secure Area Supports [Part 3 Security Specification Ver3.0 Final] Specifications.

The SQF-ISD is based on 9-pin interface, designed to operate at a maximum operating frequency of 100MHz. It can alternate communication protocol between the SD mode and SPI mode. It performs data error detection and correction with very low power consumption. Current capacity would be offered from 4GB to 64GB; it's possible to reach 2TB in the future with ex-FAT, which is called SDXC (Extended Capacity SD Memory Card).

The SQF-ISD is specifically made for any rigorous environments where devices need to be operated at extended temperature, and strong data integrity and reliability are demanded. Such environments include both industrial and automotive applications. The SQF-ISD is the best choice for exceptional reliability, excellent performance and wide compatibility.

■ **Endurance**

JEDEC defined an endurance rating TBW (TeraByte Written), following by the equation below, for indicating the number of terabytes a flash drive can be written which is a measurement of flash drive's expected lifespan, represents the amount of data written to the device.

$$TBW = [(NAND\ Endurance) \times (Flash\ Drive\ Capacity)] / WAF$$

- **NAND Endurance:** Program / Erase cycle of a NAND flash.
  - SLC: 60,000 cycles
  - Ultra MLC: 20,000 cycles
  - MLC: 3,000 cycles
- **Flash Drive Capacity:** Physical capacity in total of a Flash Drive.
- **WAF:** Write Amplification Factor (WAF), as the equation shown below, is a numerical value representing the ratio between the amount of data that a flash drive controller needs to write and the amount of data that the host's flash controller writes. A better WAF, which is near to 1, guarantees better endurance and lower frequency of data written to flash memory.

$$WAF = (Lifetime\ write\ to\ flash) / (Lifetime\ write\ to\ host)$$

The TBW rating for a flash drive shall be derived for and verified under the following workload conditions,

- Sequential Write (copy file into card)
- P/E cycles incurred: erase count after writing – erase count before writing

- (1) S: power supply, I:input; O:output using push-pull drivers; PP:I/O using push-pull drivers
- (2) The extended DAT lines (DAT1-DAT3) are input on power up. They start to operate as DAT lines after SET\_BUS\_WIDTH command. The Host shall keep its own DAT1-DAT3 lines in input mode, as well, while they are not used. It is defined so, in order to keep compatibility to MultiMedia Cards.
- (3) At power up this line has a 50KOhm pull up enabled in the card. This resistor serves two functions Card detection and Mode Selection. For Mode Selection, the host can drive the line high or let it be pulled high to select SD mode. If the host wants to select SPI mode it should drive the line low. For Card detection, the host detects that the line is pulled high. This pull-up should be disconnected by the user, during regular data transfer, with SET\_CLR\_CARD\_DETECT (ACMD42) command.

### 6.3 Power Up Time

- Host needs to keep power line level less than 0.5V and more than 1ms before power ramp up.

#### Power On or Power Cycle

Followings are requirements for Power on and Power cycle to assure a reliable SD Card hard reset.

- (1) Voltage level shall be below 0.5V
- (2) Duration shall be at least 1ms.

#### Power Supply Ramp Up

The power ramp up time is defined from 0.5V threshold level up to the operating supply voltage which is stable between VDD(min.) and VDD(max.) and host can supply SDCLK. Followings are recommendation of Power ramp up:

- (1) Voltage of power ramp up should be monotonic as much as possible.
- (2) The minimum ramp up time should be 0.1ms.
- (3) The maximum ramp up time should be 35ms for 2.7-3.6V power supply.

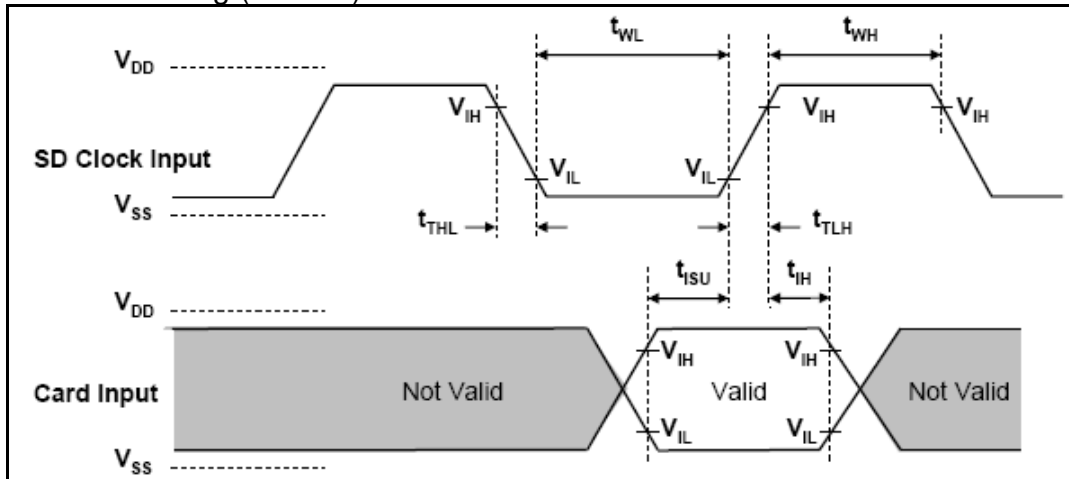

#### Power Down and Power Cycle

- When the host shuts down the power, the card VDD shall be lowered to less than 0.5Volt for a minimum period of 1ms. During power down, DAT, CMD, and CLK should be disconnected or driven to logical 0 by the host to avoid a situation that the operating current is drawn through the signal lines.
- If the host needs to change the operating voltage, a power cycle is required. Power cycle means the power is turned off and supplied again. Power cycle is also needed for accessing cards that are already in Inactive State. To create a power cycle the host shall follow the power down description before power up the card (i.e. the card VDD shall be once lowered to less than 0.5Volt for a minimum period of 1ms).
