

# OPA1637 High-Fidelity, Low-Noise, Fully-Differential, Burr-Brown™ Audio Operational Amplifier

## 1 Features

- Low input voltage noise: 3.7 nV/√Hz at 1 kHz
- Low THD + N: –120 dB at 1 kHz
- Low supply current: 950 μA at ±18 V
- Input offset voltage: ±200 μV (maximum)
- Input bias current: 2 nA (maximum)
- Low bias current noise: 400 fA/√Hz at 10 Hz
- Gain-bandwidth product: 9.2 MHz
- Differential output slew rate: 15 V/μs
- Wide input and output common-mode range
- Wide single-supply operating range: 3 V to 36 V
- Low supply current power-down feature: < 20 μA
- Overload power limit
- Current limit
- Package: 8-pin VSSOP
- Temperature range: –40°C to +125°C

## 2 Applications

- Professional audio mixer or control surface
- Professional microphones and wireless systems
- Professional speaker systems
- Professional audio amplifier
- Soundbar
- Turntable
- Professional video camera
- Guitar and other instrument amplifier
- Data acquisition (DAQ)

## 3 Description

The OPA1637 is a low-noise, low total harmonic distortion (THD), fully differential, Burr-Brown™ Audio operational amplifier that easily filters and drives fully differential, audio signal chains.

The OPA1637 also converts single-ended sources to differential outputs required by high-fidelity analog-to-digital converters (ADCs). Designed for exceptional low noise and THD, the bipolar super-beta inputs yield a very low noise figure at very-low quiescent current and input bias current. This device is designed for audio circuits where low power consumption is required along with excellent signal-to-noise ratio (SNR) and spurious-free dynamic range (SFDR).

The OPA1637 features high-voltage supply capability, allowing for supply voltages up to ±18 V. This capability allows high-voltage differential signal chains to benefit from the improved headroom and dynamic range without adding separate amplifiers for each polarity of the differential signal. Very-low voltage and current noise enables the OPA1637 for use in high-gain configurations with minimal impact to the audio signal noise.

The OPA1637 is characterized for operation over the wide temperature range of –40°C to +125°C, and is available in an 8-pin VSSOP package.

### Device Information (1)

PART NUMBER	PACKAGE	BODY SIZE (NOM)
OPA1637	VSSOP (8)	3.00 mm × 3.00 mm

- (1) For all available packages, see the package option addendum at the end of the datasheet.

Low-Noise, Low-Power, Fully-Differential Amplifier Gain Block and Interface

Low Input Voltage Noise

## 4 Revision History

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

<b>Changes from Revision A (May 2020) to Revision B (August 2020)</b>	<b>Page</b>
• Updated the numbering format for tables, figures, and cross-references throughout the document.....	1
• Changed front page application diagram to show correct label and value for $R_{F1}$ .....	1
• Changed Figure 7-1 to show correct labels.....	15
• Changed Figure 9-5 to show correct label and value for $R_{F1}$ .....	22
• Changed Figure 9-8 negative rail from 0 V to –5 V.....	24

<b>Changes from Revision * (December 2019) to Revision A (May 2020)</b>	<b>Page</b>
• Changed device status from advanced information (preview) to production data (active) .....	1

## 5 Pin Configuration and Functions

**Figure 5-1. DGK Package, 8-Pin VSSOP, Top View**

### Pin Functions

PIN		I/O	DESCRIPTION
NAME	NO.		
IN-	1	I	Inverting (negative) amplifier input
IN+	8	I	Noninverting (positive) amplifier input
OUT-	5	O	Inverting (negative) amplifier output
OUT+	4	O	Noninverting (positive) amplifier output
PD	7	I	Power down. $\overline{\text{PD}}$ = logic low = power off mode. $\overline{\text{PD}}$ = logic high = normal operation. The logic threshold is referenced to VS+. If power down is not needed, leave $\overline{\text{PD}}$ floating.
VOCM	2	I	Ouput common-mode voltage control input
VS-	6	I	Negative power-supply input
VS+	3	I	Positive power-supply input

## 6 Specifications

### 6.1 Absolute Maximum Ratings

over operating free-air temperature range (unless otherwise noted)<sup>(1)</sup>

			MIN	MAX	UNIT
V <sub>S</sub>	Supply voltage	Single supply		40	V
		Dual supply		±20	V
	IN+, IN-, Differential voltage <sup>(2)</sup>			±0.5	V
	IN+, IN-, VO <sub>CM</sub> , P <sub>D</sub> , OUT+, OUT- voltage <sup>(3)</sup>		V <sub>VS-</sub> - 0.5	V <sub>VS+</sub> + 0.5	V
	IN+, IN- current		-10	10	mA
	OUT+, OUT- current		-50	50	mA
	Output short-circuit <sup>(4)</sup>			Continuous	
T <sub>A</sub>	Operating Temperature		-40	150	°C
T <sub>J</sub>	Junction Temperature		-40	175	°C
T <sub>stg</sub>	Storage Temperature		-65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Input pins IN+ and IN- are connected with anti-parallel diodes in between the two terminals. Differential input signals that are greater than 0.5 V or less than -0.5 V must be current-limited to 10 mA or less.
- (3) Input terminals are diode-clamped to the supply rails (V<sub>S+</sub>, V<sub>S-</sub>). Input signals that swing more than 0.5 V greater or less the supply rails must be current-limited to 10 mA or less.
- (4) Short-circuit to V<sub>S</sub> / 2.

### 6.2 ESD Ratings

			VALUE	UNIT
V <sub>(ESD)</sub>	Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±1000	V
		Charged device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

### 6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

			MIN	NOM	MAX	UNIT
V <sub>S</sub>	Supply voltage	Single-supply	3		36	V
		Dual-supply	±1.5		±18	
T <sub>A</sub>	Specified temperature		-40		125	°C

### 6.4 Thermal Information

THERMAL METRIC <sup>(1)</sup>		OPA1637		UNIT
		DGK (VSSOP)		
		8 PINS		
R <sub>θJA</sub>	Junction-to-ambient thermal resistance	181.1		°C/W
R <sub>θJC(top)</sub>	Junction-to-case (top) thermal resistance	68.3		°C/W
R <sub>θJB</sub>	Junction-to-board thermal resistance	102.8		°C/W
ψ <sub>JT</sub>	Junction-to-top characterization parameter	10.6		°C/W
ψ <sub>JB</sub>	Junction-to-board characterization parameter	101.1		°C/W
R <sub>θJC(bot)</sub>	Junction-to-case (bottom) thermal resistance	N/A		°C/W

- (1) For information about traditional and new thermal metrics, see the [Semiconductor and IC Package Thermal Metrics](#) application report.

### 6.5 Electrical Characteristics

at  $T_A = 25^\circ\text{C}$ ,  $V_S$  (dual supply) =  $\pm 1.5\text{ V}$  to  $\pm 18\text{ V}$ ,  $V_{VOCM} = 0\text{ V}$ , input common mode voltage ( $V_{ICM}$ ) =  $0\text{ V}$ ,  $R_F = 2\text{ k}\Omega$ ,  $V_{PD} = V_{VS+}$ ,  $R_L = 10\text{ k}\Omega$ <sup>(1)</sup> (unless otherwise noted)

PARAMETER		TEST CONDITIONS	MIN	TYP	MAX	UNIT
<b>FREQUENCY RESPONSE</b>						
SSBW	Small-signal bandwidth	$V_O$ <sup>(2)</sup> = $100\text{ mV}_{PP}$ , $G = -1\text{ V/V}$		7		MHz
GBP	Gain-bandwidth product	$V_O = 100\text{ mV}_{PP}$ , $G = -10\text{ V/V}$		9.2		MHz
FBP	Full-power bandwidth	$V_O = -1\text{ V}_{PP}$ , $G = -1\text{ V/V}$		2.5		MHz
SR	Slew rate	$G = -1$ , 10-V step		15		V/ $\mu\text{s}$
	Settling time	0.1% of final value, $G = -1\text{ V/V}$ , $V_O = 10\text{-V step}$		1		$\mu\text{s}$
		0.01% of final value, $G = -1\text{ V/V}$ , $V_O = 10\text{-V step}$		2		
THD+N	Total harmonic distortion and noise	Differential input, $f = 1\text{ kHz}$ , $V_O = 10\text{ V}_{PP}$		-120		dB
				0.0001		%
		Single-ended input, $f = 1\text{ kHz}$ , $V_O = 10\text{ V}_{PP}$		-115		dB

## 7 Parameter Measurement Information

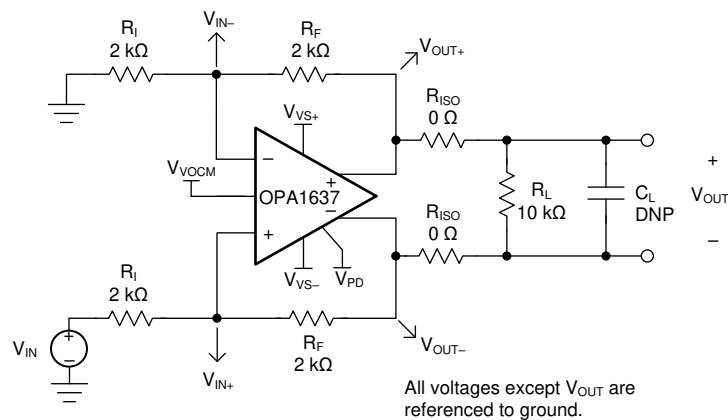

### 7.1 Characterization Configuration

The OPA1637 provides the advantages of a fully differential amplifier (FDA) configuration that offers very low noise and harmonic distortion in a single, low-power amplifier. The FDA is a flexible device, where the main aim is to provide a purely differential output signal centered on a user-configurable, common-mode voltage that is usually matched to the input common-mode voltage required by an analog-to-digital converter (ADC) or class-D amplifier. The circuit used for characterization of the differential-to-differential performance is seen in [Figure 7-1](#).

**Figure 7-1. Differential Source to a Differential Gain of a 1-V/V Test Circuit**

A similar circuit is used for single-ended to differential measurements, as shown in [Figure 7-2](#).

**Figure 7-2. Single-Ended to Differential Gain of a 1-V/V Test Circuit**

The FDA requires feedback resistor for both output pins to the input pins. These feedback resistors load the output differentially only if the input common-mode voltage is equal to the output common-mode voltage set by V<sub>O</sub>CM. When V<sub>O</sub>CM differs from the input common-mode range, the feedback resistors create single-ended loading. The characterization plots fix the R<sub>F</sub> (R<sub>F1</sub> = R<sub>F2</sub>) value at 2 kΩ, unless otherwise noted. This value can be adjusted to match the system design parameters with the following considerations in mind:

- The current needed to drive R<sub>F</sub> from the peak output voltage to the input common-mode voltage adds to the overall output load current. If the total load current (current through R<sub>F</sub> + current through R<sub>L</sub>) exceeds the current limit conditions, the device enters a current limit state, causing the output voltage to collapse.
- High feedback resistor values (R<sub>F</sub> > 100 kΩ) interact with the amplifier input capacitance to create a zero in the feedback network. Compensation must be added to account for this potential source of instability; see the [TI Precision Labs FDA Stability Training](#) for guidance on designing an appropriate compensation network.

## 8 Detailed Description

### 8.1 Overview

The OPA1637 is a low-noise, low-distortion fully-differential amplifier (FDA) that features Texas Instrument's super-beta bipolar input devices. Super-beta input devices feature very low input bias current as compared to standard bipolar technology. The low input bias current and current noise makes the OPA1637 an excellent choice for audio applications that require low-noise differential signal processing without significant current consumption. This device is also designed for analog-to-digital audio input circuits that require low noise in a single fully-differential amplifier. This device achieves lower current consumption at lower noise levels than what is achievable with two low-noise amplifiers. The OPA1637 also features high-voltage capability, which allows the device to be used in  $\pm 15\text{-V}$  supply circuits without any additional voltage clamping or regulators. This feature enables a direct, single amplifier for a 24-dBm differential output drive (commonly found on mixers and digital audio interfaces) without any additional amplification.

### 8.2 Functional Block Diagram

## 8.3 Feature Description

### 8.3.1 Super-Beta Input Bipolar Transistors

The OPA1637 is designed on a modern bipolar process that features TI's super-beta input transistors. Traditional bipolar transistors feature excellent voltage noise and offset drift, but suffer a tradeoff in high input bias current ( $I_B$ ) and high input bias current noise. Super-beta transistors offer the benefits of low voltage noise and low offset drift with an order of magnitude reduction in input bias current and reduction in input bias current noise. For audio circuits, input bias current noise can dominate in circuits where higher resistance input resistors are used. The OPA1637 enables a fully-differential, low-noise amplifier design without restrictions of low input resistance at a power level unmatched by traditional single-ended amplifiers.

### 8.3.2 Power Down

The OPA1637 features a power-down circuit to disable the amplifier when a low-power mode is required by the system. In the power-down state, the amplifier outputs are in a high-impedance state, and the amplifier total quiescent current is reduced to less than 20  $\mu\text{A}$ .

### 8.3.3 Flexible Gain Setting

The OPA1637 offers considerable flexibility in the configuration and selection of resistor values. Low input bias current and bias current noise allows for larger gain resistor values with minimal impact to noise or offset. The design starts with the selection of the feedback resistor value. The 2-k $\Omega$  feedback resistor value used for the characterization curves is a good compromise among power, noise, and phase margin considerations. With the feedback resistor values selected (and set equal on each side), the input resistors are set to obtain the desired gain, with the input impedance also set with these input resistors. Differential I/O designs provide an input impedance that is the sum of the two input resistors. Single-ended input to differential output designs present a more complicated input impedance. Most characteristic curves implement the single-ended to differential design as the more challenging requirement over differential-to-differential I/O.

### 8.3.4 Amplifier Overload Power Limit

In many bipolar-based amplifiers, the output stage of the amplifier can draw significant (several milliamperes) of quiescent current if the output voltage becomes clipped (meaning the output voltage becomes limited by the negative or positive supply voltage). This condition can cause the system to enter a high-power consumption state, and potentially cause oscillations between the power supply and signal chain. The OPA1637 has an advanced output stage design that eliminates this problem. When the output voltage reaches the  $V_{VS+}$  or  $V_{VS-}$  voltage, there is virtually no additional current consumption from the nominal quiescent current. This feature helps eliminate any potential system problems when the signal chain is disrupted by a large external transient voltage.

## 8.4 Device Functional Modes

The OPA1637 has two functional modes: normal operation and power-down. The power-down state is enabled when the voltage on the power-down pin is lowered to less than the power-down threshold. In the power-down state, the quiescent current is significantly reduced, and the output voltage is high-impedance. This high impedance can lead to the input voltages (+IN and -IN) separating, and forward-biasing the ESD protection diodes. See [Section 9](#) for guidance on power-down operation.

## 9 Application and Implementation

### Note

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 9.1 Application Information

Most applications for the OPA1637 strive to deliver the best dynamic range in a design that delivers the desired signal processing along with adequate phase margin for the amplifier. The following sections detail some of the design issues with analysis and guidelines for improved performance.

#### 9.1.1 Driving Capacitive Loads

The capacitive load of an ADC, or some other next-stage device, is commonly required to be driven. Directly connecting a capacitive load to the output pins of a closed-loop amplifier such as the OPA1637 can lead to an unstable response. One typical remedy to this instability is to add two small series resistors ( $R_{ISO}$ ) at the outputs of the OPA1637 before the capacitive load. Good practice is to leave a place for the  $R_{ISO}$  elements in a board layout (a 0- $\Omega$  value initially) for later adjustment, in case the response appears unacceptable.

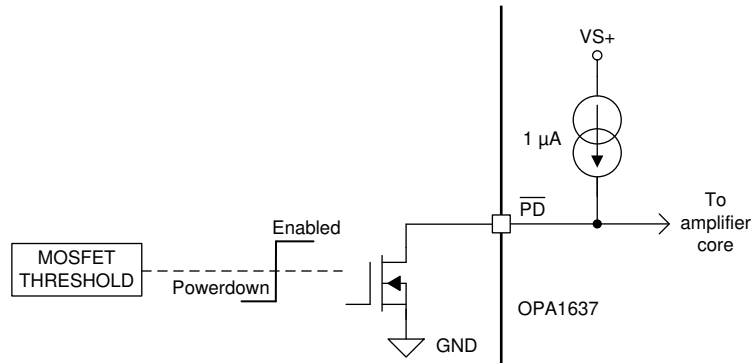

For applications where the OPA1637 is used as an output device to drive an unknown capacitive load, such as a cable,  $R_{ISO}$  is required. Figure 9-1 shows the required  $R_{ISO}$  value for a 40-degree phase-margin response. The peak required  $R_{ISO}$  value occurs when  $C_L$  is between 500 pF and 1 nF. As  $C_L$  increases beyond 1 nF, the bandwidth response of the device reduces, resulting in a slower response but no major degradation in phase margin. For a typical cable type, such as Belden 8451, capacitive loading can vary from 340 pF (10-foot cable) to 1.7 nF (50-foot cable). Selecting  $R_{ISO}$  to be 100  $\Omega$  provides sufficient phase margin regardless of the cable length.  $R_{ISO}$  can also be used within the loop feedback of the amplifier; however, simulation must be used to verify the stability of the system.

**Figure 9-1. Required Isolation Resistance vs Capacitive Load for a 40° Phase Margin**

### 9.1.2 Operating the Power-Down Feature

The power-down feature on the OPA1637 allows the device to be put into a low power-consumption state, in which quiescent current is minimized. To force the device into the low-power state, drive the  $\overline{\text{PD}}$  pin lower than the power-down threshold voltage ( $V_{\text{VS}+} - 2 \text{ V}$ ). Driving the  $\overline{\text{PD}}$  pin lower than the power-down threshold voltage forces the internal logic to disable both the differential and common-mode amplifiers. The  $\overline{\text{PD}}$  pin has an internal pullup current that allows the pin to be used in an open-drain MOSFET configuration without an additional pullup resistor, as seen in Figure 9-2. In this configuration, the logic level can be referenced to the MOSFET, and the voltage at the  $\overline{\text{PD}}$  pin is level-shifted to account for use with high supply voltages. Be sure to select an N-type MOSFET with a maximum  $B_{\text{VDSS}}$  greater than the total supply voltage. For applications that do not use the power-down feature, tie the  $\overline{\text{PD}}$  pin to the positive supply voltage.

**Figure 9-2. Power-Down ( $\overline{\text{PD}}$ ) Pin Interface With Low-Voltage Logic Level Signals**

When  $\overline{PD}$  is low (device is in power down) the output pins will be in a high-impedance state. When the device is in the power-down state, the outputs are high impedance, and the output voltage is no longer controlled by the amplifier, but dependant on the input and load configuration. In this case, the input voltage between  $IN-$  and  $IN+$  can drift to a voltage that may forward-bias the input protection diodes. Take care to avoid high currents flowing through the input diodes by using an input resistor to limit the current to less than 10 mA. In [Figure 9-3](#), the OPA1637 is configured in a differential gain of 5 with 100- $\Omega$  input resistors. When the device enters power down, the voltage between  $IN-$  and  $IN+$  increases until the internal protection diode is forward-biased. In this case, exceeding a voltage on  $V_{IN}$  with  $R_{IN} = 0 \Omega$  of 2.5 V (diode forward voltage estimated at 0.5 V) results in a current greater than 10 mA. To avoid this high current, select  $R_{IN}$  so that the maximum current flow is less than 10 mA when  $V_{IN}$  is at maximum voltage.

**Figure 9-3. Path of Input Current Flow When  $\overline{PD} = \text{Low}$**

### 9.1.3 I/O Headroom Considerations

The starting point for most designs is to assign an output common-mode voltage for the OPA1637. For ac-coupled signal paths, this voltage is often the default midsupply voltage to retain the most available output swing around the voltage centered at the  $V_{OCM}$  voltage. For dc-coupled designs, set this voltage with consideration to the required minimum headroom to the supplies, as described in the specifications for the  $V_{OCM}$  control. For precision ADC drivers, this  $V_{OCM}$  output becomes the  $V_{CM}$  input to the ADC. Often,  $V_{CM}$  is set to  $V_{REF} / 2$  to center the differential input on the available input when precision ADCs are being driven.

From target output  $V_{OCM}$ , the next step is to verify that the desired output differential peak-to-peak voltage,  $V_{OUTPP}$ , stays within the supplies. For any desired differential  $V_{OUTPP}$ , make sure that the absolute maximum voltage at the output pins swings with [Equation 1](#) and [Equation 2](#), and confirm that these expressions are within the supply rails minus the output headroom required for the RRO device.

$$V_{OUTMIN} = V_{OCM} - \frac{V_{OUTPP}}{4} \quad (1)$$

$$V_{OUTMAX} = V_{OCM} + \frac{V_{OUTPP}}{4} \quad (2)$$

With the output headroom confirmed, the input junctions must also stay within the operating range. The input range limitations require a maximum 1.0-V headroom from the supply voltages ( $V_{S+}$  and  $V_{S-}$ ) over the full temperature range.

### 9.1.4 Noise Performance

The first step in the output noise analysis is to reduce the application circuit to the simplest form with equal feedback and gain setting elements to ground. Figure 9-4 shows the simplest analysis circuit with the FDA and resistor noise terms to be considered.

**Figure 9-4. FDA Noise Analysis Circuit**

The noise powers are shown in Figure 9-4 for each term. When the  $R_F$  and  $R_G$  (or  $R_I$ ) terms are matched on each side, the total differential output noise is the root sum squared (RSS) of these separate terms. Using  $NG \equiv 1 + R_F / R_G$ , the total output noise is given by Equation 3. Each resistor noise term is a  $4kT \times R$  power ( $4kT = 1.6E-20$  J at 290 K).

$$e_o = \sqrt{(e_{ni}NG)^2 + 2(i_{n+}R_F)^2 + 2(4kTR_FNG)} \quad (3)$$

The first term is simply the differential input spot noise times the noise gain. The second term is the input current noise terms times the feedback resistor (and because there are two uncorrelated current noise terms, the power is two times one of them). The last term is the output noise resulting from both the  $R_F$  and  $R_G$  resistors, at again, twice the value for the output noise power of each side added together. Running a wide sweep of gains when holding  $R_F$  to 2 k $\Omega$  gives the standard values and resulting noise listed in Table 9-1. When the gain increases, the input-referred noise approaches only the gain of the FDA input voltage noise term at 3.7 nV/ $\sqrt{\text{Hz}}$ .

**Table 9-1. Swept Gain of the Output- and Input-Referred Spot Noise Calculations**

GAIN (V/V)	$R_F$ ( $\Omega$ )	$R_{G1}$ ( $\Omega$ )	$A_V$	$E_O$ (nV/ $\sqrt{\text{Hz}}$ )	$E_I$ (nV/ $\sqrt{\text{Hz}}$ )
0.1	2000	20000	0.1	9.4	93.9
1	2000	2000	1	13.6	13.6
2	2000	1000	2	17.8	8.9
5	2000	402	4.98	29.5	5.9
10	2000	200	10	48.6	4.9

## 9.2 Typical Applications

### 9.2.1 Current-Output Audio DAC Buffer to Class-D Amplifier

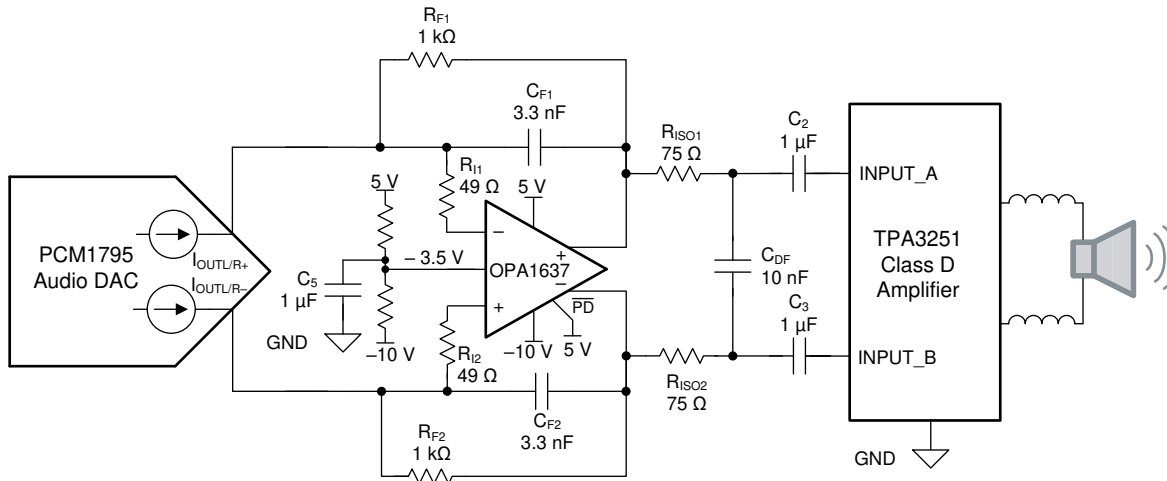

Figure 9-5. Differential Current-to-Voltage Converter

#### 9.2.1.1 Design Requirements

The requirements for this application are:

- Differential current-to-voltage conversion and filtering
- 1-kmho transimpedance gain
- 40-kHz Butterworth response filter
- 0-V dc common-mode voltage at DAC output

#### 9.2.1.2 Detailed Design Procedure

This design provides current-to-voltage conversion from a current-output audio DAC into a voltage-input, class-D amplifier. The order of design priorities are as follows:

- Select feedback-resistor values based on the gain required from the current-output stage to the voltage-input stage. For this design, the full-scale, peak-to-peak output current of the PCM1795 ( $I_{OUTL/R+} - I_{OUTL/R-}$ ) is  $\pm 4$  mA. A gain of 1k gives a wide voltage swing of  $\pm 4$  V, allowing for high SNR without exceeding the input voltage limit of the TPA3251.
- After the gain is fixed, select the output common-mode voltage. The output common-mode voltage determines the input common-mode voltage in this configuration. To set the nominal output voltage of the PCM1795 to 0 V (which corresponds to the input common mode voltage of the OPA1637), shift the output negatively from the desired common-mode input voltage by the gain multiplied by the dc center current value of the PCM1795 (3.5 mA). In this case,  $-3.5$  V satisfies the design goal.
- A bypass capacitor from the VOVM pin to ground must be selected to filter noise from the voltage divider. The capacitor selection is determined by balancing the startup time of the system with the output common-mode noise. A higher capacitance gives a lower frequency filter cutoff on the VOVM pin, thus giving lower noise performance, but also slows down the initial startup time of the circuit as a result of the RC delay from the resistor divider in combination with the filter capacitor.
- Select  $C_F$  so that the desired bandwidth of the active filter is achieved. The 3-dB frequency is determined by the reciprocal of the product of  $R_F$  and  $C_F$ .
- Use a passive filter on the output to increase noise filtering beyond the desired bandwidth. The passive filter formed by  $R_{D1,2}$  and  $C_{DF}$  adds an additional real pole to the filter response. If the pole is designed at the same frequency as the active filter pole, the overall 3-dB frequency shifts to a lower frequency value, and the step response is overdamped. A trade-off must be made to give optimal transient response versus increased filter attenuation at higher frequencies. For this design, the second pole is set to 106 kHz.

### 9.2.1.3 Application Curves

The simulated response of the current-to-voltage audio DAC buffer can be seen in [Figure 9-6](#) and [Figure 9-7](#).

## 9.2.2 An MFB Filter Driving an ADC Application

A common application use case for fully-differential amplifiers is to easily convert a single-ended signal into a differential signal to drive a differential input source, such as an ADC or class-D amplifier. Figure 9-8 shows an example of the OPA1637 used to convert a single-ended, low-voltage signal audio source, such as a small electret microphone, and deliver a low-noise differential signal that is common-mode shifted to the center of the ADC input range. A multiple-feedback (MFB) configuration is used to provide a Butterworth filter response, giving a 40-dB/decade rolloff with a  $-3$ -dB frequency of 30 kHz.

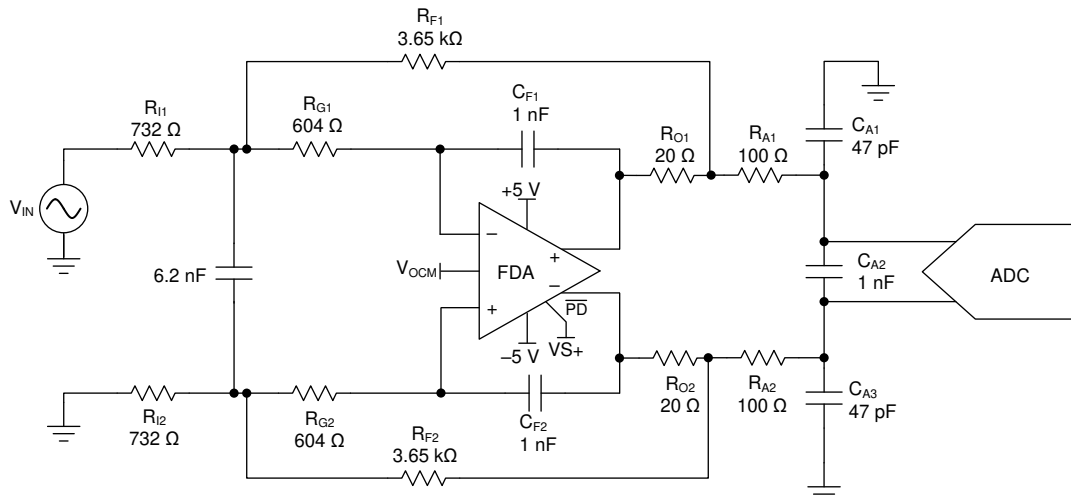

Figure 9-8. Example 30-kHz Butterworth Filter

### 9.2.2.1 Design Requirements

The requirements for this application are:

- Single-ended to differential conversion
- 5-V/V gain
- Active filter set to a Butterworth, 30-kHz response shape
- Output RC elements set by SAR input requirements (not part of the filter design)
- Filter element resistors and capacitors are set to limit added noise over the OPA1637 and noise peaking

### 9.2.2.2 Detailed Design Procedure

The design proceeds using the techniques and tools suggested in the [Design Methodology for MFB Filters in ADC Interface Applications application note](#). The process includes:

- Scale the resistor values to not meaningfully contribute to the output noise produced by the OPA1637.
- Select the RC ratios to hit the filter targets when reducing the noise gain peaking within the filter design.
- Set the output resistor to 100  $\Omega$  into a 1-nF differential capacitor.
- Add 47-pF common-mode capacitors to the load capacitor to improve common noise filtering.
- Inside the loop, add 20- $\Omega$  output resistors after the filter feedback capacitor to increase the isolation to the load capacitor.

### 9.2.2.3 Application Curves

The gain and phase plots are shown in [Figure 9-9](#). The MFB filter features a Butterworth responses feature very flat passband gain, with a 2-pole roll-off at 30 kHz to eliminate any higher-frequency noise from contaminating the signal chain, and potentially alias back into the audio band.

**Figure 9-9. Gain and Phase Plot for a 30-kHz Butterworth Filter**

### 9.2.3 Differential Microphone Input to Line Level

Professional dynamic microphones typically feature low output impedance to minimize noise coupling on the microphone cable. Interfacing the microphone with high-impedance circuitry typically requires the use of an impedance conversion stage, often done with a transformer or discrete amplifiers. The flexibility of the OPA1637 allows the device to be configured with a low differential input impedance and 20 dB of gain, simplifying the impedance conversion and gain stage into a single device. Figure 9-10 shows an example of a differential, low input impedance, microphone level voltage (10 mV to 100 mV) amplifier to a line-level amplitude signal that also has adjustable dc common-mode shift capability. This design example shows how the OPA1637 makes a great choice for driving an ADC class-D amplifier.

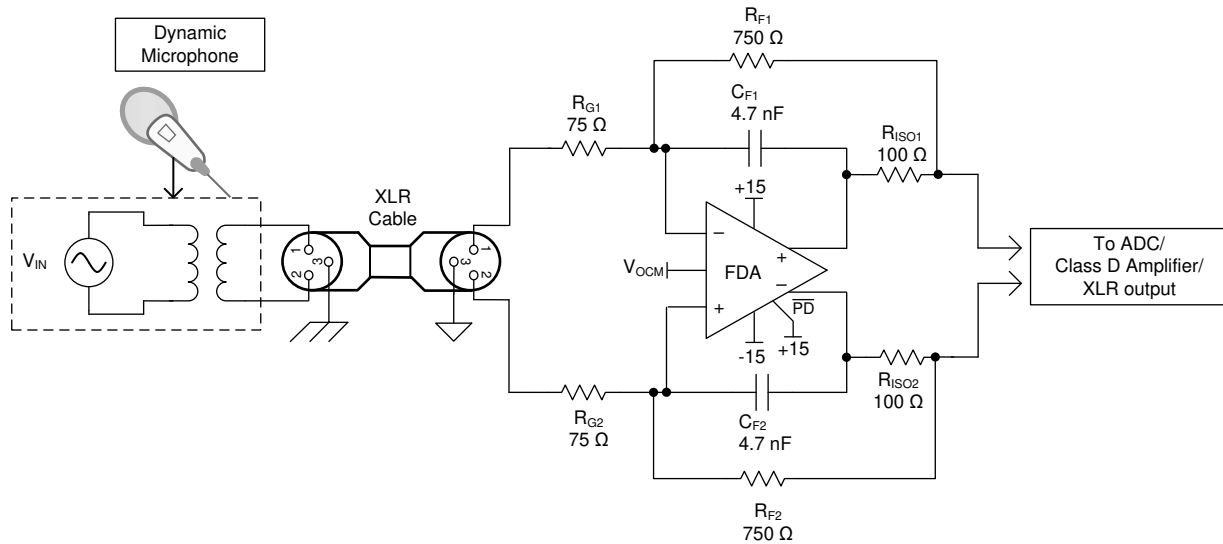

Figure 9-10. Fully Differential, Low-Noise, 20-dB Microphone Gain Block With DC Shift

#### 9.2.3.1 Application Curves

Figure 9-11. Output Waveform of the Microphone Amplifier

## 10 Power Supply Recommendations

The OPA1637 operates from supply voltages of 3.0 V to 36 V ( $\pm 1.5$  V to  $\pm 18$  V, dual supply). Connect ceramic bypass capacitors from both VS+ and VS– to GND.

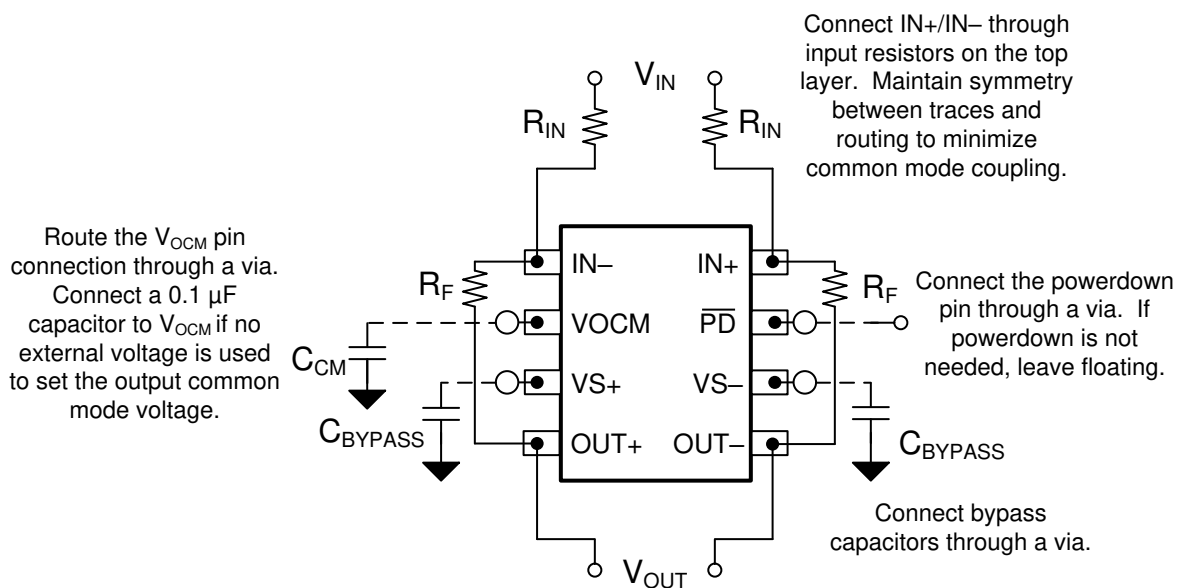

## 11 Layout

### 11.1 Layout Guidelines

#### 11.1.1 Board Layout Recommendations

- Keep differential signals routed together to minimize parasitic impedance mismatch.
- Connect a 0.1- $\mu$ F capacitor to the supply nodes through a via.
- Connect a 0.1- $\mu$ F capacitor to the VO<sub>CM</sub> pin if no external voltage is used.
- Keep any high-frequency nodes that can couple through parasitic paths away from the VO<sub>CM</sub> node.
- Clean the PCB board after assembly to minimize any leakage paths from excess flux into the VO<sub>CM</sub> node.

#### 11.2 Layout Example

**Figure 11-1. Example Layout**

### 12.3 Receiving Notification of Documentation Updates

To receive notification of documentation updates, navigate to the device product folder on [ti.com](http://ti.com). Click on *Subscribe to updates* to register and receive a weekly digest of any product information that has changed. For change details, review the revision history included in any revised document.

### 12.4 Support Resources

[TI E2E™ support forums](#) are an engineer's go-to source for fast, verified answers and design help — straight from the experts. Search existing answers or ask your own question to get the quick design help you need.

Linked content is provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

### 12.5 Trademarks

Burr-Brown™ and TI E2E™ are trademarks of Texas Instruments. All other trademarks are the property of their respective owners.

### 12.6 Electrostatic Discharge Caution

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

### 12.7 Glossary

[TI Glossary](#) This glossary lists and explains terms, acronyms, and definitions.

## 13 Mechanical, Packaging, and Orderable Information

The following pages include mechanical, packaging, and orderable information. This information is the most current data available for the designated devices. This data is subject to change without notice and revision of this document. For browser-based versions of this data sheet, refer to the left-hand navigation.

**PACKAGING INFORMATION**

Orderable Device	Status (1)	Package Type	Package Drawing	Pins	Package Qty	Eco Plan (2)	Lead finish/ Ball material (6)	MSL Peak Temp (3)	Op Temp (°C)	Device Marking (4/5)	Samples
OPA1637DGKR	ACTIVE	VSSOP	DGK	8	2500	RoHS & Green	NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	1637	<a href="#">Samples</a>
OPA1637DGKT	ACTIVE	VSSOP	DGK	8	250	RoHS & Green	NIPDAUAG	Level-2-260C-1 YEAR	-40 to 125	1637	<a href="#">Samples</a>

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
