1 Introduction

The DIYAMP-SC70-EVM is an EVM developed to give users the ability to easily evaluate their design concepts. This break-apart EVM has several popular op-amp configurations including: amplifiers, filters, and stability compensation configurations for both single and dual supply. The EVM is designed for 0805 and 0603 package size surface mount components enabling easy prototyping. This board gives the user the ability to build anything from a simple amplifier to complex signal chains by combining different configurations.

For more information about power supply voltages and input/output limitations, consult TI Precision Labs – Op Amps videos.

2 Hardware Setup

Assembly of the DIYAMP-SC70-EVM involves identifying and breaking out the desired circuit configuration from the EVM, soldering components, header pins, and inputs and outputs connections. This section presents the details of these procedures.

2.1 EVM Circuit Locations

Figure 1 and Table 2 map the location of each circuit configuration on the EVM. Figure 1 labels each circuit configuration with a letter ranging from A to L. Table 2 matches the circuit configuration to a letter in Figure 1 and also provides the name of each individual circuit written in silk screen on the EVM.

2.2 EVM Assembly Instructions

This section has step-by-step instructions on how to assemble a circuit configuration from the EVM.

Step 1. Choose the desired circuit configuration. See Section 2.1 for the location of each circuit configuration.

Step 2. Gently flex the PCB panel at the score lines to separate the desired circuit configuration from the EVM.

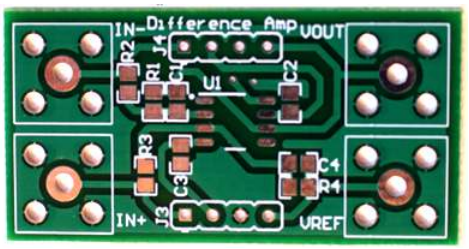

Figure 2. Detach Desired Circuit Configuration

Step 3. Solder device and surface mount passive components to the separated PCB.

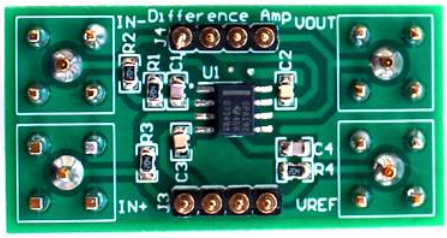

Figure 3. Detach Configuration With Attached IC and Passive Components

Step 4. Use long-nose pliers to break header strips, provided in the EVM kit, into 4-position lengths.

3.2 Single-Supply, Multiple Feedback Filter

Figure 9 shows the schematic for the single-supply, multiple feedback (MFB) filter circuit configuration.

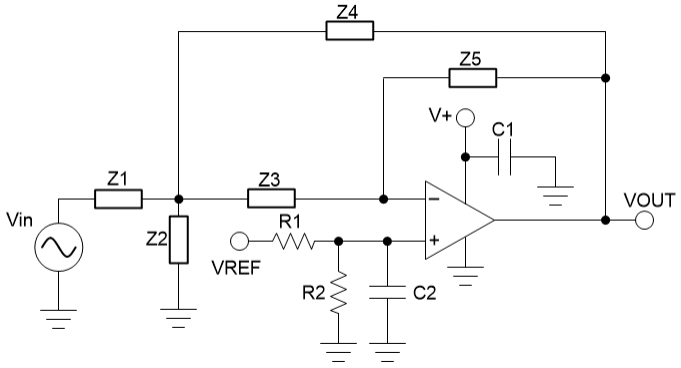

Figure 9. Single-Supply, Multiple Feedback Filter Schematic

The MFB topology (sometimes called infinite gain or Rauch) is often preferred, due to low sensitivity to component variations. The MFB topology creates an inverting second-order stage. This inversion may, or may not, be a concern in the filter application.

The single-supply, MFB filter circuit can be configured as a low-pass filter, high-pass filter, or band-pass filter based on the component selection of Z1 through Z5. Table 3 displays the type of passive component that should be chosen for Z1 through Z5 for each filter configuration.

3.3 Single-Supply, Sallen-Key Filter

Figure 12 shows the schematic for the single-supply, Sallen-Key filter circuit configuration.

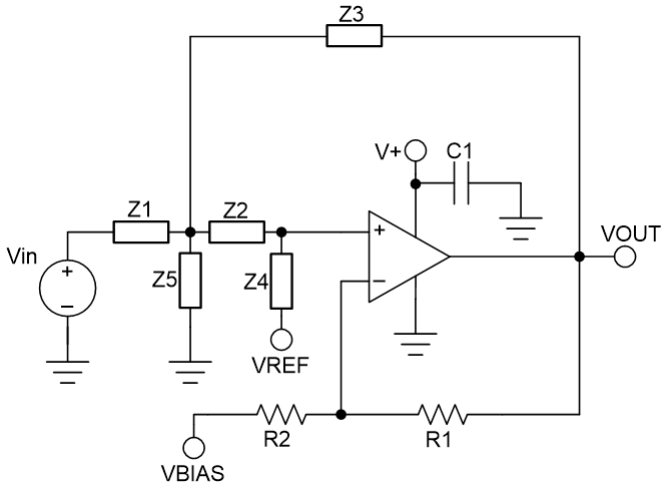

Figure 12. Single-Supply, Sallen-Key Filter Schematic

Sallen-Key is one of the most commonly applied active filter topologies. The Sallen-Key is a non-inverting, voltage-controlled, voltage-source (VCVS) able to attain larger Qs with a stable response than other filter topologies. Because Sallen-Key is non-inverting, it might be preferable over the MFB topology.

The single-supply, Sallen-Key filter can be configured as a low-pass filter, high-pass filter, or band-pass filter based on the component selection of Z1 through Z5. Table 4 displays the type of passive component that should be chosen for Z1 through Z5 for each filter configuration.

3.4 Single-Supply, Non-Inverting Amplifier

Figure 15 shows the schematic for the single-supply, non-inverting amplifier circuit configuration.

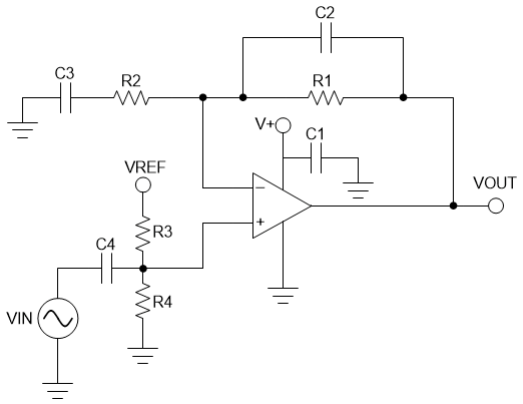

Figure 15. Single-Supply, Non-Inverting Amplifier Schematic

The non-inverting op-amp configuration takes an input signal that is applied directly to the high impedance, non-inverting input terminal and outputs a signal that is the same polarity as the input signal. The load resistance for this topology is the sum of R1 and R2. The values of the resistors in the feedback network will determine the amount of gain to amplify the input signal.

There are multiple ways to configure the single-supply, non-inverting amplifier. The following cases show three primary use case configurations for this circuit.

Copyright © 2017, Texas Instruments Incorporated

Case 1: Standard non-inverting circuit

This circuit board can be configured into a standard non-inverting circuit by shorting C3 and C4 with a 0-Ω resistor and leaving R3 and R4 unpopulated.

Equation 2 displays the transfer function for the standard single-supply, non-inverting amplifier circuit configuration.

$$V_{out} = \left(1 + \frac{R_1}{R_2}\right) V_{in} \tag{2}$$

where

- C3 is shorted with a 0-Ω resistor
- C4 is shorted with a 0-Ω resistor
- R3 is unpopulated
- R4 is unpopulated

Capacitor C2 provides the option to filter the output. The cutoff frequency of the filter can be calculated using Equation 3.

$$f_c = \frac{1}{2\pi \times R_1 \times C_2} \tag{3}$$

Case 2: AC coupled, single-supply, non-inverting circuit

This circuit board can be configured into an AC coupled non-inverting circuit by populating C3 and C4 with capacitors and populating R3 or R4 with resistors. R3 and R4 are used to set the DC output in the following two ways:

Option 1: VREF is directly applied to the input IN+

- R3 is populated with the desired biasing resistor
- R4 is unpopulated

Option 2: VREF is divided down and applied to the input IN+

- R3 and R4 are populated with resistors, see Equation 4

$$V_{IN+} = \left(\frac{R_4}{R_3 + R_4}\right) V_{ref} \tag{4}$$

The AC response of the input signal is high-passed through C4, R3 + R4. The op-amp noise-gain is unity-gain until the gain begins to rise at the zero frequency defined in Equation 5.

$$F_{ZERO} = \frac{1}{2\pi \times C_3 (R_1 + R_2)} \tag{5}$$

The gain flattens off to the same gain defined in Equation 2 at the frequency defined in Equation 6.

$$F_{pole} = \frac{1}{2\pi \times C_3 \times R_2} \tag{6}$$

For more information on the AC coupled non-inverting circuit, see e2e.ti.com.

Case 3: Non-inverting signal scaling circuit

This circuit board can be configured into a non-inverting signal scaling circuit by shorting C3 with a 0-Ω resistor and populating C4 with a resistor. This forms a 3-resistor divider with R3 and R4 on the input to scale or shift the input signal level. The op amp is typically configured as a unity-gain buffer.

Step 1. Choose a value for the resistor installed in place of C4

Step 2. Compute R3

$$R_3 = \frac{\left(1 + \frac{R_1}{R_2}\right) C_4 \times V_{ref}}{V_{offset}} \tag{7}$$

Copyright © 2017, Texas Instruments Incorporated

Step 3. Compute R2

$$R_2 = \frac{-V_{offset} \times C_4 \times R_3}{V_{offset} \times R_3 + V_{offset} \times C_4 - V_{ref} \times C_4} \quad (8)$$

For more information on the AC coupled non-inverting circuit, see e2e.ti.com.

3.5 Single-Supply, Inverting Amplifier

Figure 18 shows the schematic for the single-supply, inverting amplifier circuit configuration.

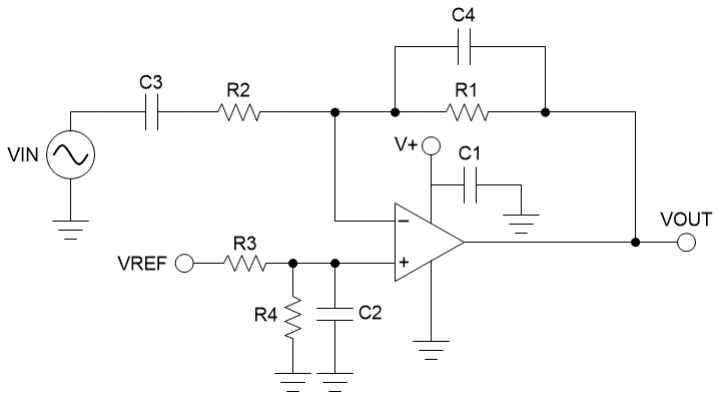

Figure 18. Single-Supply, Inverting Amplifier Schematic

The inverting op-amp configuration takes an input signal that is applied directly to the inverting input terminal and outputs a signal that is the opposite polarity as the input signal. The benefit of this topology is that it avoids common mode limitations. The load resistance for this topology is equal to R2. The values of the resistors in the feedback network will determine the amount of gain to amplify the input signal.

The single-supply, inverting amplifier circuit provides the option to AC couple the input, filter the output, and bias the output of the amplifier to a desired value.

Equation 9 displays the dc transfer function of the single-supply, inverting amplifier circuit configuration.

$$V_{out} = \left(-\frac{R_1}{R_2}\right) V_{in} + \left(1 + \frac{R_1}{R_2}\right)\left(\frac{R_4}{R_3 + R_4}\right) V_{ref} \quad (9)$$

where

- C3 is shorted with a 0-Ω resistor

Capacitor C3 provides the option to AC couple the input of the single-supply, inverting amplifier by creating a high-pass filter. Equation 10 displays the dc transfer function of the single-supply, inverting amplifier circuit configuration.

$$V_{out} = \left(\frac{R_4}{R_3 + R_4}\right) V_{ref} \quad (10)$$

where

- The input is AC coupled with C3

The cutoff frequency of the high-pass filter can be calculated using Equation 11.

$$f_{c_highpass} = \frac{1}{2\pi \times C_3 \times R_2} \quad (11)$$

Equation 12 displays the transfer function when the frequency of the input signal is above the cutoff frequency calculated in Equation 11.

$$V_{out} = \left(-\frac{R_1}{R_2}\right) V_{in} + \left(\frac{R_4}{R_3 + R_4}\right) V_{ref} \quad (12)$$

Capacitor C2 filters noise that may be introduced from the Vref input. Equation 13 calculates the cutoff frequency due to C2.

$$f_{c_Vref} = \frac{1}{2\pi \times R_3 \,//\, R_4 \times C_2} \quad (13)$$

Capacitor C4 provides the option to filter the output. The cutoff frequency of the filter can be calculated using Equation 14.

$$f_{c_Vout} = \frac{1}{2\pi \times R_1 \times C_4} \quad (14)$$

3.6 Difference Amplifier

Figure 21 shows the schematic for the difference amplifier circuit configuration.

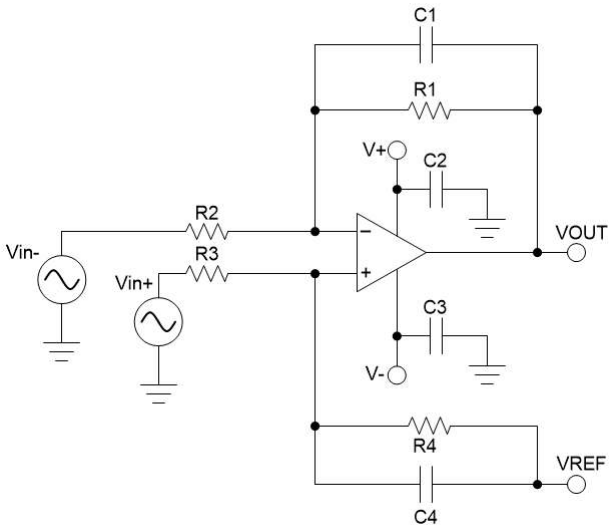

Figure 21. Difference Amplifier Schematic

The difference amplifier utilizes both inverting and non-inverting inputs and produces an output that is equal to the difference between the inputs. The gain of the difference amplifier is dependent on the ratio of the resistor values selected.

Equation 15 displays the transfer function of the difference amplifier circuit configuration.

$$V_{out} = \left(\frac{R_4}{R_3 + R_4}\right)\left(1 + \frac{R_1}{R_2}\right) V_{IN+} + \left(\frac{R_3}{R_3 + R_4}\right)\left(1 + \frac{R_1}{R_2}\right) V_{ref} + \frac{R_1}{R_2} V_{IN-} \quad (15)$$

If $R_1 = R_4$ and $R_2 = R_3$, Equation 15 can be simplified to Equation 16.

$$V_{out} = \frac{R_1}{R_2}\left(V_{IN+} - V_{IN-}\right) + V_{ref} \quad (16)$$

Copyright © 2017, Texas Instruments Incorporated

Capacitors C1 and C4 provide the option to filter the output of the amplifier. The cutoff frequency of the filter can be calculated using Equation 17.

$$f_c = \frac{1}{2\pi \times R_1 \times C_1} \quad (17)$$

where

- $R_1 = R_4$, $R_2 = R_3$, and $C_1 = C_4$

3.7 Dual-Supply, Multiple Feedback Filter

Figure 24 shows the schematic for the dual-supply, multiple feedback filter circuit configuration.

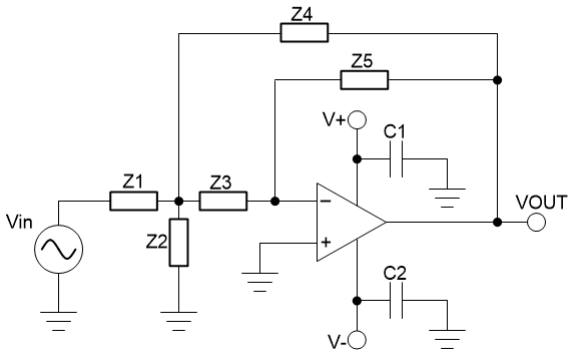

Figure 24. Dual-Supply, Multiple Feedback Filter Schematic

The MFB topology (sometimes called infinite gain or Rauch) is often preferred due to low sensitivity to component variations. The MFB topology creates an inverting second-order stage. This inversion may, or may not, be a concern in the filter application.

The dual-supply, MFB filter circuit can be configured as a low-pass filter, high-pass filter, or band-pass filter based on the component selection of Z1 through Z5. Table 5 displays the type of passive component that should be chosen for Z1 through Z5 for each filter configuration.

Table 5. MFB Filter Type Component Selection

Pass-Band Filter Type	Type of Component (Z1)	Type of Component (Z2)	Type of Component (Z3)	Type of Component (Z4)	Type of Component (Z5)

3.8 Dual-Supply, Sallen-Key Filter

Figure 27 shows the schematic for the dual-supply, Sallen-Key Filter circuit configuration.

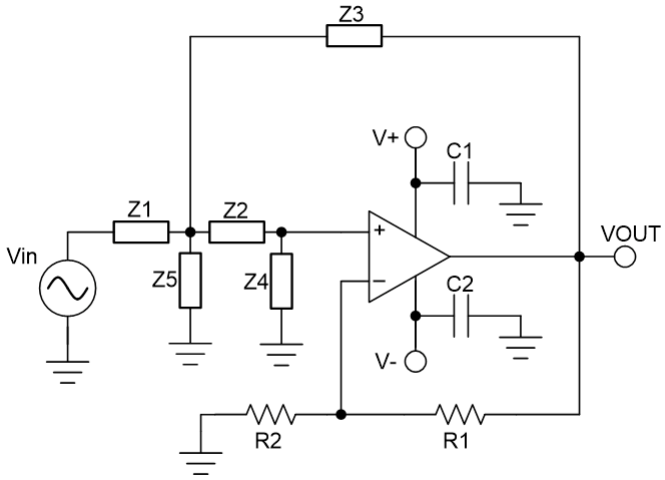

Figure 27. Dual-Supply, Sallen-Key Filter Schematic

Sallen-Key is one of the most commonly applied active filter topologies. The Sallen-Key is a non-inverting, voltage-controlled, voltage-source (VCVS) able to attain larger Qs with a stable response than other filter topologies. Because Sallen-Key is non-inverting, it might be preferable over the MFB topology.

For this EVM, the Sallen-key filter can be configured for unity-gain by populating R1 with a short and leaving R2 open. Gain can be added by adding the appropriate resistors to R2 and R1 as explained in FilterPro.

The dual-supply, Sallen-Key filter can be configured as a low-pass filter, high-pass filter, or band-pass filter based on the component selection of Z1 through Z5. Table 6 displays the type of passive component that should be chosen for Z1 through Z5 for each filter configuration.

3.9 Inverting Comparator

Figure 30 shows the schematic for the inverting comparator circuit configuration.

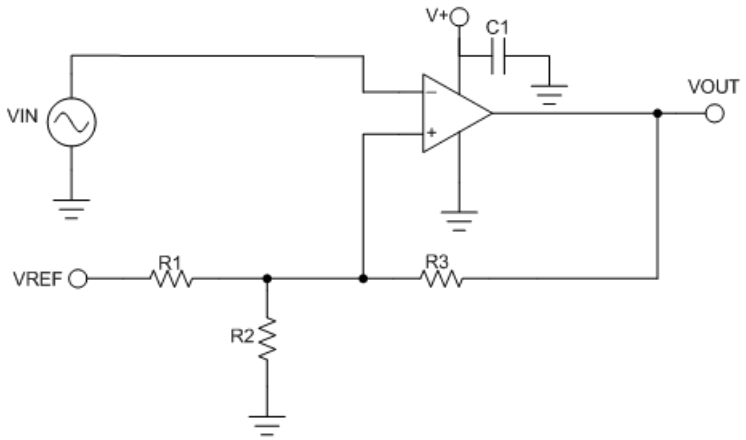

Figure 30. Inverting Comparator Schematic

It is important to note that this circuit layout is meant for SC70 package op amps or push-pull output type comparators. This configuration uses a voltage divider R1 and R2 to set up the threshold voltage when no hysteresis is added. The comparator will compare the input signal (Vin) to the threshold voltage (Vth).

$$V_{th} = \left(\frac{R_2}{R_1 + R_2} \right) V_{ref} \quad (18)$$

where

- R3 is unpopulated

The comparator input signal is applied to the inverting input, so the output will have an inverted polarity. When Vin > Vth, the output will drive to the negative supply (GND or logic low). When Vin < Vth, the output will drive to the positive supply (V+ or logic high).

R3 can be populated to implement hysteresis which uses two different threshold voltages to avoid the multiple transitions. The input signal must exceed the upper threshold (VH) to transition low or below the lower threshold (VL) to transition high. Equation 19 and Equation 20 will calculate the value of R2 and R3 for the two desired thresholds.

$$R_3 = \left(\frac{V_L}{V_H - V_L} \right) R_1 \quad (19)$$

$$R_2 = \left(\frac{V_L}{V_+ - V_H} \right) R_1 \quad (20)$$

The PCB layout of the top layer of the inverting comparator circuit configuration is displayed in Figure 31.

3.10 Non-Inverting Comparator

Figure 33 shows the schematic for the non-inverting comparator circuit configuration.

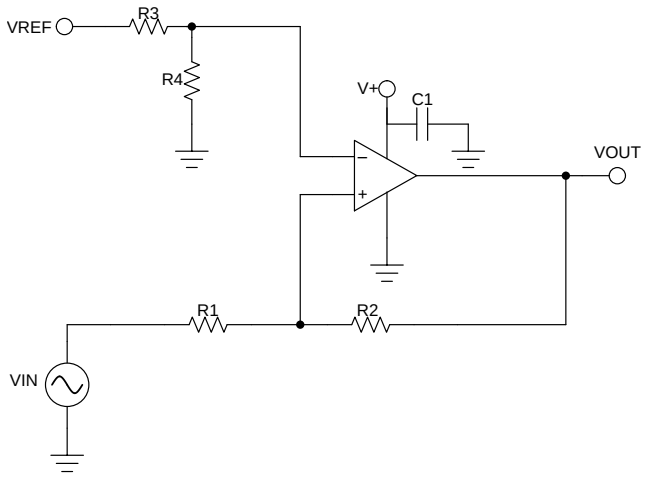

Figure 33. Non-Inverting Comparator Schematic

It is important to note that this circuit layout is meant for SC70 package op amp or push-pull output type comparators. This configuration uses a voltage divider R3 and R4 to set up the threshold voltage. The comparator will compare the input signal (Vin) to the threshold voltage (Vth).

$$V_{th} = \left(\frac{R_4}{R_3 + R_4} \right) V_{ref} \tag{21}$$

The comparator input signal is applied to the non-inverting input, so the output will have a non-inverted polarity. When Vin > Vth, the output will drive to the positive supply (V+ or logic high). When Vin < Vth, the output will drive to the negative supply (GND or logic low).

R2 can be populated to implement hysteresis which uses two different threshold voltages to avoid the multiple transitions. The input signal must exceed the upper threshold (VH) to transition high or below the lower threshold (VL) to transition low. Equation 22 and Equation 23 will calculate the value of R1 and R2 for the two desired thresholds.

$$R_1 = \frac{(V_h - V_{th})}{V_{th}} R_2 \tag{22}$$

$$R_2 = \frac{(V_{th} + V_+)}{(V_l - V_{th})} R_1 \tag{23}$$

3.11 R_{iso} With Dual Feedback

Figure 36 shows the schematic for the R_{iso} with dual-feedback circuit configuration.

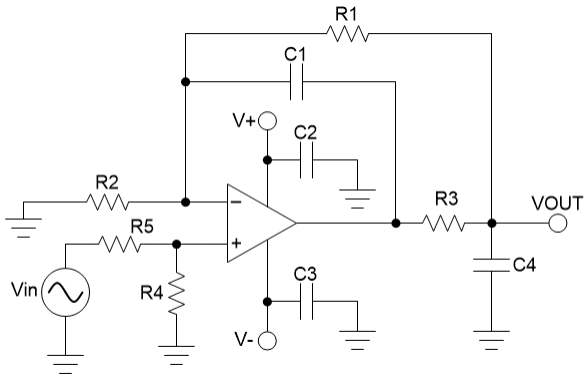

Figure 36. R_{iso} with Dual-Feedback Schematic

The dc gain of the R_{iso} with dual-feedback circuit configuration can be calculated using Equation 24.

$$V_{out} = \left(1 + \frac{R_1}{R_2}\right)\left(\frac{R_4}{R_4 + R_5}\right)V_{in} \quad (24)$$

Copyright © 2017, Texas Instruments Incorporated

In situations where stability is affected by capacitive loads, the R_{iso} dual-feedback configuration has the ability to stabilize the circuit by compensating the contribution of the capacitive load to circuit instability. This capacitive load compensation technique uses an isolation resistor that compensates the circuit by adding a zero to cancel the pole from the output impedance and capacitive load. Refer to the *TI Precision Labs - Op Amps: Stability 5* video for detailed information on this technique.

The design steps for the R_{iso} method follow:

1. Use TINA-TI™ to find the zero frequency, f_{ZERO}, where A_{OL_Loaded} = 20 dB (example shown in Figure 37).

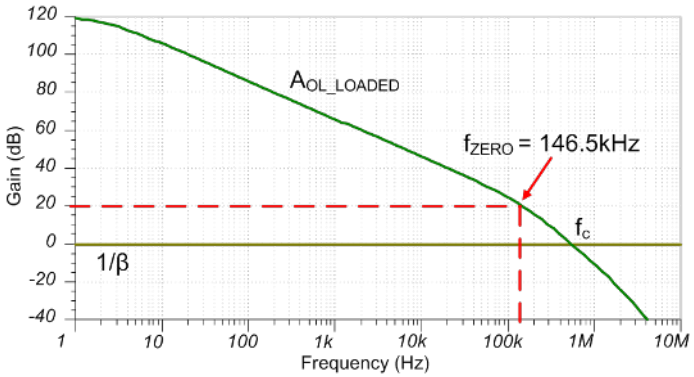

Figure 37. Example of f_{ZERO}, Where A_{OL_Loaded} = 20 dB

2. Calculate R_{iso} to set the zero at f_{ZERO} – this will yield between 60° and 90° of phase margin

$$R_{iso} = \frac{1}{2\pi \times f_{ZERO} \times C_{Load}} \quad (25)$$

where

- R_{iso} = R3
- C_{Load} = C4

While the R_{iso} circuit is both simple to implement and design, it has a big disadvantage in precision circuits. The voltage drop from R_{iso} is dependent on the output current or output load, and may be significant compared to the desired signal.

The second capacitive load compensation technique uses the R_{iso} with dual-feedback stability compensation method. The R_{iso} dual-feedback circuit solves the voltage drop disadvantage of the previously stated R_{iso}. Refer to the *TI Precision Labs - Op Amps: Stability 6* video for detailed information on this technique.

Design steps for the R_{iso} method follow:

1. R_{iso} using Method 1: R_{iso} techniques
2. Set R1: $R_1 \geq (R_{iso} \times 100)$
3. Set C_1: $\frac{6R_{iso} \times C_{Load}}{R_1} \leq C_1 \leq \frac{10R_{iso} \times C_{Load}}{R_1}$

Using this range ensures that the two feedback paths, R_2 and C_3, will never create a resonance that would cause instability. Smaller values of C3 will result in faster settling time at the expense of overshoot for certain load ranges. While the R_{iso} dual-feedback circuit solves the dc accuracy issue with the R_{iso} circuit, it has some disadvantages as well. The disadvantage of this method is that the circuit is not as tolerant to changes in the output capacitance and can quickly become unstable. Therefore, the R_{iso} dual-feedback circuit is best for situations where the output capacitance is known and will not vary significantly. This method generally results in a slower settling time than the R_{iso} circuit as well.

Figure 40 shows the schematic for the dual-supply, non-inverting amplifier circuit configuration.

The non-inverting op-amp configuration takes an input signal that is applied directly to the high impedance non-inverting input terminal and outputs a signal that is the same polarity as the input signal. The load resistance for this topology is the sum of R1 and R2. The values of the resistors in the feedback network will determine the amount of gain to amplify the input signal.

Equation 26 displays the transfer function of the dual-supply, non-inverting amplifier circuit configuration shown in Figure 40.

$$V_{out} = \left(1 + \frac{R_1}{R_2}\right) V_{in} \tag{26}$$

Capacitor C3 provides the option to filter the output. The cutoff frequency of the filter can be calculated using Equation 27.

$$f_c = \frac{1}{2\pi \times R_1 \times C_3} \tag{27}$$

3.13 Dual-Supply, Inverting Amplifier

Figure 43 shows the schematic for the dual-supply, inverting amplifier circuit configuration.

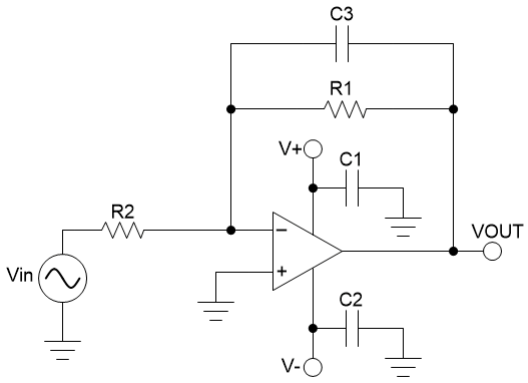

Figure 43. Dual-Supply, Inverting Amplifier Schematic

The inverting op-amp configuration takes an input signal that is applied directly to the inverting input terminal and outputs a signal that is the opposite polarity as the input signal. The benefit of this topology is that it avoids common mode limitations. The load resistance for this topology is equal to R2. The values of the resistors in the feedback network will determine the amount of gain to amplify the input signal.

Equation 28 displays the transfer function for the dual-supply, inverting amplifier circuit configuration shown in Figure 43.

$$V_{out} = -\frac{R_1}{R_2} V_{in} \tag{28}$$

Capacitor C3 provides the option to filter the output. The cutoff frequency of the filter can be calculated using Equation 29.

$$f_c = \frac{1}{2\pi \times R_1 \times C_3} \tag{29}$$

4 Connections

This section provides a description for each connection available on the EVM.

4.1 Inputs and Outputs

The input/output connection slots were designed to fit the following connections: vertical SMA, horizontal SMA, wires, or through-hole test points. Examples of these four connectors are shown in this section.

The SMA recommended for this board is TE Connectivity part number 5-1814400-1.

Figure 46 shows SMA vertical connectors attached to both the input and output terminal.

Figure 49 shows a through-hole test point connector attached to the output and Vref terminal.

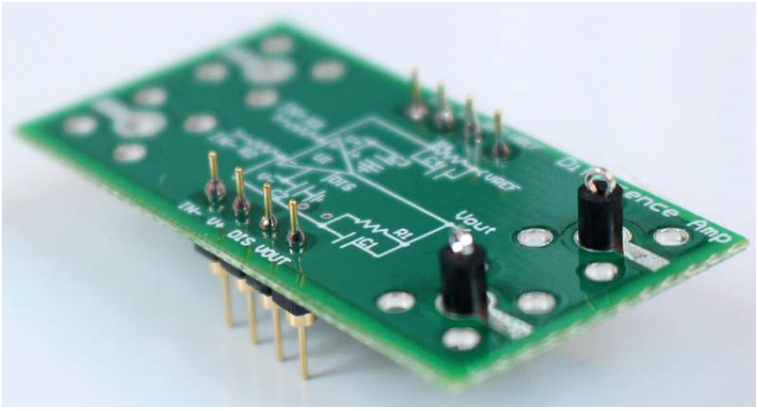

Figure 49. Through-Hole Test Points

The input and output connections can also be accessed from the header strip. The input connections are labeled IN+ and IN- for the non-inverting and inverting inputs, respectively. The output connection is labeled VOUT. An example highlighting the input and output is shown in Figure 50.

4.2 Power

This EVM features both dual- and single-supply, op-amp configurations. Power can only be applied using the header pins located at the top and bottom of the PCB. The positive supply is labeled V+, the negative supply is labeled V–, and ground is labeled GND. As an alternative, wire can be used in place of the included terminals strips to power the board directly. Figure 51 shows an all-wire assembly for a multiple feedback filter configuration.

4.3 Enable and Disable Feature

The DIYAMP-SC70-EVM provides a means to test the shutdown feature for op-amp devices equipped with a shutdown pin. The access to the shutdown pin, labeled SD, is located on the terminal area.
