DESCRIPTION

• **Fault Mode Selection** The ONET4211LD is a laser driver for multiple fiber **Bias and Photodiode Current Monitors b** optic applications up to 4.25 Gbps. The device accepts CML input data and provides bias and **CML Data Inputs**
 CML Data Inputs modulation currents for driving a laser diode. Also
 Temperature Compensation of Modulation

provided are automatic power control (APC). provided are automatic power control (APC), **Current Current C** fault detection, and current monitor features. • **Single 3.3-V Supply**

Surface-Mount, Small-Footprint, 4 mm \times **4 mm** \cdots **The device is available in a small-footprint, 4 mm** \times **4 24-Lead QFN Package** mm 24-pin QFN package. The circuit requires a single 3.3-V supply.

> This power-efficient laser driver is characterized for operation from –40°C to 85°C.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

These devices have limited built-in ESD protection. The leads should be shorted together or the device placed in conductive foam during storage or handling to prevent electrostatic damage to the MOS gates.

DETAILED DESCRIPTION

BLOCK DIAGRAM

A simplified block diagram of the ONET4211LD is shown in Figure 1.

This compact, low-power, 4.25-Gbps laser driver circuit consists of a high-speed data path and a bias-and-control block.

The function of the data path is to buffer the input data and then modulate the laser diode current according to the input data stream.

The bias-and-control block generates the laser diode bias current, contains automatic power control (APC) to maintain constant optical output power, generates a modulation current that can be temperature compensated, and controls power on during start-up and shutdown after failure detection. The circuit design is optimized for high-speed and low-voltage operation (3.3 V).

The main circuit blocks are described in detail in the following paragraphs.

HIGH-SPEED DATA PATH

The high-speed data path consists of an input buffer stage and a current modulator.

The input buffer stage takes CML-compatible differential signals. It provides on-chip, 50-Ω termination to VCC. AC-coupling may be used at the DIN+ and DIN- inputs.

The laser diode current modulator consists mainly of two common-emitter output transistors and the required driver circuitry. According to the input data stream, the modulation current is sunk at the MOD+ or the MOD– pin.

Modulation current setting is performed by means of the modulation current generator block, which is supervised by the control circuit block.

The laser diode can be either ac- or dc-coupled. In either case, the maximum modulation current is 85 mA. The modulation output is optimized for driving a 20-Ω load.

For optimum power efficiency, the laser driver does not provide any on-chip back-termination.

BIAS AND CONTROL

The bias-and-control circuitry consists of the bandgap voltage and bias generation block, the bias current generator, the automatic power control block, and the supervising control circuitry.

BANDGAP VOLTAGE AND BIAS GENERATION

The bandgap voltage reference provides the process- and temperature-independent reference voltages needed to set bias current, modulation current, and photodiode reference current. Additionally, this block provides the biasing for all internal circuits.

AUTOMATIC POWER CONTROL

The ONET4211LD laser driver incorporates an APC loop to compensate for the changes in laser threshold current over temperature and lifetime. The internal APC is enabled when resistors are connected to the IBMAX and APCSET pins. A back-facet photodiode mounted in the laser package is used to detect the average laser output power. The photodiode current I_{PD} that is proportional to the average laser power can be calculated by using the laser-to-monitor transfer ratio, ρ_{MON} and the average power, P_{AVG} :

$$
I_{PD}[A] = P_{AVG}[W] \times \rho_{MON}[A/W]
$$
\n(1)

In closed-loop operation, the APC modifies the laser diode bias current by comparing I_{PD} with a reference current I_{APCSFT} and generates a bias compensation current. I_{PD} can be programmed by selecting the external resistor R_{APCSET} according to:

$$
R_{\text{APCSET}}[\Omega] = \frac{4.69 \text{ V}}{I_{\text{PD}}[\text{A}]} = \frac{4.69 \text{ V}}{P_{\text{AVG}}[\text{W}] \times \rho_{\text{MON}}[\text{A/W}]}
$$
(2)

The bias compensation current subtracts from the maximum bias current to maintain the monitor photodiode current. The maximum bias current is programmed by the resistor connected to IBMAX:

$$
I_{BIASMAX}[A] = \frac{343 \text{ V}}{R_{BIASMAX}[\Omega]}
$$
\n(3)

An external pin, MONB, is provided as a bias current monitor output. A fraction of the bias current (1/68) is mirrored and develops a voltage drop across an external resistor to ground, R_{MONB} . The voltage at MONB is given as:

$$
V_{\text{MONB}}[V] = \frac{R_{\text{MONB}}[\Omega] \times I_{\text{BIAS}}[A]}{68} \tag{4}
$$

If the voltage at MONB is greater than the programmed threshold, a fault mode occurs.

MONP is also provided as a photocurrent monitor output. The photodiode current, I_{PD} , is mirrored and develops a voltage across an external resistor to ground, R_{MONP} . The voltage at MONP is given as:

$$
V_{\text{MONP}}[V] = R_{\text{MONP}}[\Omega] \times I_{\text{PD}}[A] \tag{5}
$$

If the voltage at MONP is greater than the programmed threshold, a fault mode occurs.

As with any negative-feedback system design, care must be taken to ensure stability of the loop. The loop bandwidth must not be too high, in order to minimize pattern-dependent jitter. The dominant pole is determined by the capacitor C_{APC} . The recommended value for C_{APC} is 200 nF. The capacitance of the monitor photodiode C_{PD} adds another pole to the system, and thus it must be small enough to maintain stability. The recommended value for this capacitance is $C_{PD} \leq 50$ pF.

The internal APC loop can be disabled by connecting a 100-kΩ resistor from APCSET to VCC and leaving PD open. In open-loop operation, the laser diode current is set by $I_{BIASMAX}$ and I_{MODSET} .

MODULATION CURRENT GENERATOR

The modulation current generator defines the tail current of the modulator, which is sunk from either MOD+ or MOD–, depending on the data pattern. The modulation current consists of a current I_{MOD0} at a reference temperature $T_0 = 60^{\circ}$ C (set by the resistor R_{MODSET}) and a temperature-dependent modulation current defined by the resistor R_{MODTC} . The modulation current can be estimated as follows:

$$
I_{\text{MOD}}[A] = \frac{265 \text{ V}}{R_{\text{MODSET}}[\Omega]} \times \left[1 + \left(\frac{24 \Omega}{R_{\text{MODTC}}[\Omega]} + 630 \text{ ppm} \right) \times \left(T[^{\circ}C] - T_0[^{\circ}C] \right) \right]
$$
(6)

Note that the reference temperature, T_0 , and the temperature compensation set by R_{MODTC} vary from part to part. To reduce the variation, I_{MOD} can be calibrated over temperature and set with a microcontroller DAC or digital potentiometer.

CONTROL

The function of this block is to control the start-up sequence, detect faults, detect tracking failure of the APC loop, and provide disable control. The laser driver has a controlled start-up sequence which helps prevent transient glitches from being applied to the laser during power on. At start-up, the laser diode is off, SDOWN is low, and the APC loop is open. Once V_{CC} reaches ~2.8 V, the laser diode bias generator and modulation current generator circuitry are activated (if DISABLE is low). The slow-start circuitry gradually brings up the current delivered to the laser diode. From the time when V_{CC} reaches ~2.8 V until the modulation current and bias current reach 95% of their steady state value, is considered the initialization time. If DISABLE is asserted during power on, the slow-start circuitry does not activate until DISABLE is negated.

FAULT DETECTION

The fault detection circuitry monitors the operation of the ONET4211LD. If FLTMODE is set to a low level, (hard-fault mode) this circuitry disables the bias and modulation circuits and latches the SDOWN output on detection of a fault. The fault mode is reset by toggling DISABLE (for a minimum time of T_{RES}) or by toggling VCC.

Once DISABLE is toggled, SDOWN is set low and the circuit is re-initialized.

If FLTMODE is set to a high level (soft-fault mode), a fault is indicated at the SDOWN output; however, the bias and modulation circuits are not disabled. The SDOWN output is reset once the fault-causing condition disappears. Toggling DISABLE or VCC is not required.

A functional representation of the fault-detection circuitry is shown in [Figure 2.](#page-4-0)

Figure 2. Functional Representation of the Fault Detection Circuitry

A fault mode is produced if the laser cathode is grounded and the photocurrent causes MONP to exceed its programmed threshold. Another fault mode can be produced if the laser diode end-of-life condition causes excessive bias current and photocurrent that results in monitor voltages (MONP, MONB) being greater than their programmed threshold. Other fault modes can occur if there are any I/O pin single-point failures (short to VCC or GND) and the monitor voltages exceed their programmed threshold (see [Table 1](#page-5-0)).

Table 1. Response to I/O-Pin Shorts to VCC or GND

PACKAGE

For the ONET4211LD, a small-footprint, 4-mm \times 4-mm, 24-lead QFN package is used, with a lead pitch of 0,5 mm. The pinout is shown in [Figure 3.](#page-6-0)

To achieve the required low thermal resistance of about 38 K/W, which keeps the maximum junction temperature below 115°C, a good thermal connection of the exposed die pad is mandatory.

Figure 3. Pinout of the ONET4211LD in a 4-mm \times 4-mm, 24-Lead QFN Package (Top View)

TERMINAL FUNCTIONS

ABSOLUTE MAXIMUM RATINGS

over operating free-air temperature range (unless otherwise noted)⁽¹⁾

(1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute–maximum–rated conditions for extended periods may affect device reliability.

(2) All voltage values are with respect to network ground terminal.

APPLICATION INFORMATION

Figure 25 shows the ONET4211LD connected with a dc-coupled interface to the laser diode; alternatively, the ONET4211LD laser driver can be ac-coupled.

Figure 25. Basic Application Circuit With DC-Coupled Interface Between the ONET4211LD and the Laser Diode

APC loop instability can occur with large inductive loading on the BIAS pin. To ensure loop stability in this case, it is recommended to connect a 1-nF capacitor to ground at the BIAS pin.

SELECT A LASER

In the design example according to [Figure 25,](#page-16-0) the ONET4211LD is dc-coupled to a typical communication-grade laser diode capable of operating at 4.25 Gb/s with the following specifications shown in Table 2.

SELECT APCSET RESISTOR

When the APC loop is activated, the desired average optical output power P_{AVG} is defined by characteristics of the monitor diode and by the APCSET resistor R_{APCSET} . The relation between the monitor photodiode current I_{PD} and the average optical output power P_{AVG} is given by Equation 7:

$$
I_{PD}[A] = P_{AVG}[W] \times \rho_{MON}[A/W]
$$
\n(7)

The R_{APCSET} resistor is calculated by Equation 8:

$$
R_{\text{APCSET}}[\Omega] = \frac{4.69 \text{ V}}{I_{\text{PD}}[\text{A}]} = \frac{4.69 \text{ V}}{P_{\text{AVG}}[\text{W}] \times \rho_{\text{MON}}[\text{A/W}]}
$$
(8)

For the laser diode specified in Table 2 and the desired average optical output power of 5 mW, R_{APCSET} is calculated as in Equation 9:

$$
R_{\text{APCSET}}[\Omega] = \frac{4.69 \text{ V}}{P_{\text{AVG}}[W] \times \rho_{\text{MON}}[A/W]} = \frac{4.69 \text{ V}}{5 \text{ mW} \times 0.05 \text{ mA/mW}} = 18.75 \text{ k}\Omega
$$
\n(9)

Note that the monitor photodiode current I_{PD} must not exceed 1.5 mA, corresponding to a minimum APCSET resistor $R_{APCSFT MIN}$ = 3.1 kΩ.

SELECT MODSET RESISTOR

Modulation current I_{MOD} is dependent on the required optical output peak-to-peak power P_{p-p} or the average optical power P_{AVG}. I_{MOD} can be calculated using the laser slope efficiency η and the desired extinction ratio r_e:

$$
I_{\text{MOD}}[A] = \frac{P_{p-p}[W]}{\eta[W/A]} = \frac{2 \times P_{\text{AVG}}[W] \times \frac{r_{e^{-1}}}{r_{e^{+1}}}}{\eta[W/A]}
$$
(10)

Using the laser diode parameters from Table 2 and assuming an extinction ratio $r_e = 8$ dB (X6.3) for an average optical power $P_{AVG} = 5$ mW, the required modulation current results as:

$$
I_{\text{MOD}} = \frac{2 \times 5 \text{ mW} \times \frac{6.3 - 1}{6.3 + 1}}{0.2 \text{ mW/mA}} = 36.3 \text{ mA}
$$
\n(11)

The modulation current is adjustable, with a selectable temperature coefficient TC according to the relation:

$$
I_{\text{MOD}}[A] = I_{\text{MODO}}[A] \times \left(1 + TC \times \left(T[^{\circ}C] - T_0[^{\circ}C]\right)\right)
$$
\n(12)

where T is the ambient temperature in °C and T₀ is the reference temperature (T₀ = 60°C).

The temperature coefficient TC of the modulation current is typically adjustable between 630 ppm/°C and 8300 ppm/°C.

For calculation of the required external resistor R_{MODSET} for a given modulation current and a given temperature, the formula can be modified as follows:

(13)

SLLS688A–NOVEMBER 2005–REVISED SEPTEMBER 2007

$$
R_{\text{MODSET}}[\Omega] = \frac{265 \text{ V}}{I_{\text{MOD}}[A]} \times \left(1 + TC \times \left(T[^{\circ}C] - T_0[^{\circ}C]\right)\right)
$$

If 4000 ppm/°C is the desired temperature coefficient and the modulation current from the preceding example, 36.3 mA, is required at a temperature of 25°C, the MODSET resistor R_{MODSET} is given by Equation 14.

$$
R_{\text{MODSET}}[\Omega] = \frac{265 \text{ V}}{36.3 \text{ mA}} \times \left(1 + \frac{4000 \text{ ppm}}{^{\circ}\text{C}} \times (25^{\circ}\text{C} - 60^{\circ}\text{C})\right) = 6.3 \text{ k}\Omega
$$
\n(14)

Note that the modulation current I_{MOD} must not exceed 85 mA over the complete temperature range, corresponding to a minimum MODSET resistor $R_{MODSET, MIN} = 3.1$ kΩ.

SELECT MODTC RESISTOR

The R_{MODTC} resistor is used to program a modulation temperature coefficient that can be used to compensate for the decreased slope efficiency of the laser at a higher temperature. The temperature coefficient TC_{LD} of the laser can be calculated using the slope efficiency η_1 at temperature T_1 and η_2 at temperature T_2 as shown in Equation 15:

$$
TC_{LD} \left[\frac{1}{^{0}C} \right] = \frac{\eta_{2} [W/A] - \eta_{1} [W/A]}{\eta_{1} [W/A] \times \left(T_{2} [^{0}C] - T_{1} [^{0}C] \right)} \times 10^{6}
$$
\n(15)

As an example, for the laser in [Table 2,](#page-17-0) the slope efficiency at temperature $T_1 = 25^{\circ}$ C is $n_1 = 0.2$ mW/mA. At temperature T₂ = 85°C, the slope efficiency is η_2 = 0.15 mW/mA. The corresponding temperature coefficient TC_{LD} of the laser can be calculated:

$$
TC_{LD} = \frac{0.15 \text{ mW/mA} - 0.2 \text{ mW/mA}}{0.2 \text{ mW/mA} \times (85 \text{°C} - 25 \text{°C})} \times 10^6 = -4167 \frac{1}{\text{°C}}
$$
(16)

The MODTC resistor R_{MODTC} can be used to compensate the laser temperature coefficient TC_{LD} in order to maintain the same optical output swing within a range of 630 ppm up to 8300 ppm. For this, R_{MODTC} may be programmed as follows:

$$
R_{\text{MODTC}} = \frac{24 \Omega}{(TC - 630 \text{ ppm}) \times \left[\frac{1}{\text{0C}}\right] \times \text{°C}}
$$
\n(17)

To compensate for the decreased slope efficiency of the laser in [Table 2](#page-17-0), TC must be 4167 ppm/°C.

This leads to the following MODTC resistor R_{MODTC} :

$$
R_{\text{MODTC}} = \frac{24 \Omega}{\frac{4167 \text{ ppm} - 630 \text{ ppm}}{^{\circ}\text{C}}} = 6.8 \text{ k}\Omega
$$
\n(18)

SELECT BIASMAX RESISTOR

The BIASMAX resistor $R_{B|ASMAX}$ is used to limit the bias current applied to the laser diode.

To calculate R_{BIASMAX}, the maximum threshold current at 85°C and end of life must be determined. The maximum bias current for the dc-coupled interface can be approximated by Equation 19.

$$
I_{\text{BIASMAX}}[A] = I_{\text{THMAX}}[A]
$$
\n(19)

R_{BIASMAX} can be set by Equation 20.

$$
R_{BIASMAX}[\Omega] = \frac{343 \text{ V}}{I_{BIASMAX}[A]} = \frac{343 \text{ V}}{I_{THMAX}[A]}
$$
(20)

For the example laser diode, the maximum threshold current is 40 mA at 85°C. Therefore, $R_{BIASMAX}$ can be approximated by [Equation 21.](#page-19-0)

IEXAS RUMENTS www.ti.com

(21)

$$
R_{\text{BIASMAX}} = \frac{343 \text{ V}}{40 \text{ mA}} = 8.6 \text{ k}\Omega
$$

SELECT V_{MONB} AND V_{MONP} RANGE

Monitoring the bias current is achieved by taking the fractional (1/68) bias current and developing a voltage across an external resistor to ground. Equation 22 provides the value for V_{MONB} for a resistor value equal to 768 Ω.

$$
V_{MONB}[V] = \frac{R_{MONB}[\Omega] \times I_{BIAS}[A]}{68} = \frac{768 \Omega \times I_{BIAS}[A]}{68} = 11.29 \Omega \times I_{BIAS}[A]
$$
(22)

Monitoring of the photo current is achieved by taking a mirror of I_{PD} and developing a voltage across an external resistor to ground. Equation 23 provides the value for V_{MONP} for a resistor equal to 200 Ω.

$$
V_{\text{MONP}}[V] = R_{\text{MONP}}[\Omega] \times I_{\text{PD}}[A] = 200 \Omega \times I_{\text{PD}}[A]
$$
\n(23)

LASER DIODE INTERFACE

The output stage of the ONET4211LD is optimized for driving a $20-\Omega$ load. The combination of a damping resistor, R_D, along with the resistance of the laser diode, must be 20 Ω for impedance matching. The suggested typical value for R_D is 6 Ω to 15 Ω. A bypass capacitor of 10 nF placed close to the laser anode also helps to optimize performance.

Revision History

www.ti.com 10-Dec-2020

PACKAGING INFORMATION

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

⁽²⁾ RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
