**Single-Supply Rail-to-Rail Amplifiers**

The EL5144 series amplifiers are voltage-feedback, high speed, rail-to-rail amplifiers designed to operate on a single +5V supply. They offer unity gain stability with an unloaded -3dB bandwidth of 100MHz. The input common-mode voltage range extends from the negative rail to within 1.5V of the positive rail. Driving a 75W double terminated coaxial cable, the EL5144 series amplifiers drive to within 150mV of either rail. The 200V/ $\mu$ s slew rate and 0.1%/0.1° differential gain/differential phase makes these parts ideal for composite and component video applications. With their voltage feedback architecture, these amplifiers can accept reactive feedback networks, allowing them to be used in analog filtering applications. These amplifiers will source 90mA and sink 65mA.

The EL5146 and EL5246 have a power-savings disable feature. Applying a standard TTL low logic level to the CE (Chip Enable) pin reduces the supply current to 2.6 $\mu$ A within 10ns. Turn-on time is 500ns, allowing true break-before-make conditions for multiplexing applications. Allowing the CE pin to float or applying a high logic level will enable the amplifier.

For applications where board space is critical, singles are offered in a 5 Ld SOT-23 package, duals in 8 Ld and 10 Ld MSOP packages, and quads in a 16 Ld QSOP package. Singles, duals, and quads are also available in industry standard pinouts in SO and PDIP packages. All parts operate over the industrial temperature range of -40°C to +85°C.

**Features**

- Rail-to-rail output swing
- -3dB bandwidth = 100MHz
- Single-supply +5V operation
- Power-down to 2.6 $\mu$ A
- Large input common-mode range  $0V < V_{CM} < 3.5V$
- Diff gain/phase = 0.1%/0.1°
- Low power 35mW per amplifier
- Space-saving SOT23-5, 8 Ld MSOP and 10 Ld MSOP, and 16 Ld QSOP packages
- Pb-Free available (RoHS compliant)

**Applications**

- Video amplifiers
- 5V analog signal processing
- Multiplexers
- Line drivers
- Portable computers
- High speed communications
- Sample and hold amplifiers
- Comparators

**Description of Operation and Applications Information**

**Product Description**

The EL5144 series is a family of wide bandwidth, single supply, low power, rail-to-rail output, voltage feedback operational amplifiers. The family includes single, dual, and quad configurations. The singles and duals are available with a power-down pin to reduce power to 2.6µA typically. All the amplifiers are internally compensated for closed loop feedback gains of +1 or greater. Larger gains are acceptable but bandwidth will be reduced according to the familiar Gain Bandwidth Product.

Connected in voltage follower mode and driving a high impedance load, the EL5144 series has a -3dB bandwidth of 100MHz. Driving a 150Ω load, they have a -3dB bandwidth of 60MHz while maintaining a 200V/µs slew rate. The input common mode voltage range includes ground while the output can swing rail-to-rail.

**Power Supply Bypassing and Printed Circuit Board Layout**

As with any high-frequency device, good printed circuit board layout is necessary for optimum performance. Ground plane construction is highly recommended. Lead lengths should be as short as possible. The power supply pin must be well bypassed to reduce the risk of oscillation. For normal single supply operation, where the GND pin is connected to the ground plane, a single 4.7µF tantalum capacitor in parallel with a 0.1µF ceramic capacitor from V<sub>S</sub> to GND will suffice. This same capacitor combination should be placed at each supply pin to ground if split supplies are to be used. In this case, the GND pin becomes the negative supply rail.

For good AC performance, parasitic capacitance should be kept to a minimum. Use of wire wound resistors should be avoided because of their additional series inductance. Use of sockets, particularly for the SO package, should be avoided if possible. Sockets add parasitic inductance and capacitance that can result in compromised performance.

**Input, Output and Supply Voltage Range**

The EL5144 series has been designed to operate with a single supply voltage of 5V. Split supplies can be used so long as their total range is 5V.

The amplifiers have an input common mode voltage range that includes the negative supply (GND pin) and extends to within 1.5V of the positive supply (V<sub>S</sub> pin). They are specified over this range.

The output of the EL5144 series amplifiers can swing rail to rail. As the load resistance becomes lower in value, the ability to drive close to each rail is reduced. However, even with an effective 150Ω load resistor connected to a voltage halfway between the supply rails, the output will swing to within 150mV of either rail.

Figure 48 shows the output of the EL5144 series amplifier swinging rail to rail with R<sub>F</sub> = 1kΩ, A<sub>V</sub> = +2 and R<sub>L</sub> = 1MΩ. Figure 49 is with R<sub>L</sub> = 150Ω.

FIGURE 48.

FIGURE 49.

### Choice of Feedback Resistor, $R_F$

These amplifiers are optimized for applications that require a gain of +1. Hence, no feedback resistor is required.

However, for gains greater than +1, the feedback resistor forms a pole with the input capacitance. As this pole becomes larger, phase margin is reduced. This causes ringing in the time domain and peaking in the frequency domain. Therefore,  $R_F$  has some maximum value that should not be exceeded for optimum performance. If a large value of  $R_F$  must be used, a small capacitor in the few picofarad range in parallel with  $R_F$  can help to reduce this ringing and peaking at the expense of reducing the bandwidth.

As far as the output stage of the amplifier is concerned,  $R_F + R_G$  appear in parallel with  $R_L$  for gains other than +1. As this combination gets smaller, the bandwidth falls off.

Consequently,  $R_F$  also has a minimum value that should not be exceeded for optimum performance.

For  $A_V = +1$ ,  $R_F = 0\Omega$  is optimum. For  $A_V = -1$  or +2 (noise gain of 2), optimum response is obtained with  $R_F$  between  $300\Omega$  and  $1k\Omega$ . For  $A_V = -4$  or +5 (noise gain of 5), keep  $R_F$  between  $300\Omega$  and  $15k\Omega$ .

### Video Performance

For good video signal integrity, an amplifier is required to maintain the same output impedance and the same frequency response as DC levels are changed at the output. This can be difficult when driving a standard video load of  $150\Omega$ , because of the change in output current with DC level. A look at Figures 25 through 32 beginning on page 10 (Differential Gain and Differential Phase curves for various supply and loading conditions) will help you obtain optimal performance. Curves are provided for  $A_V = +1$  and +2, and  $R_L = 150\Omega$  and  $10k\Omega$  tied both to ground as well as 2.5V. As with all video amplifiers, there is a common mode sweet spot for optimum differential gain/differential phase. For example, with  $A_V = +2$  and  $R_L = 150\Omega$  tied to 2.5V, and the output common mode voltage kept between 0.8V and 3.2V, dG/dP is a very low 0.1%/0.1°. This condition corresponds to driving an AC-coupled, double terminated  $75\Omega$  coaxial cable. With  $A_V = +1$ ,  $R_L = 150\Omega$  tied to ground, and the video level kept between 0.85V and 2.95V, these amplifiers provide dG/dP performance of 0.05%/0.20°. This condition is representative of using the EL5144 series amplifier as a buffer driving a DC coupled, double terminated,  $75\Omega$  coaxial cable. Driving high impedance loads, such as signals on computer video cards, gives similar or better dG/dP performance as driving cables.

### Driving Cables and Capacitive Loads

The EL5144 series amplifiers can drive 50pF loads in parallel with  $150\Omega$  with 4dB of peaking and 100pF with 7dB of peaking. If less peaking is desired in these applications, a small series resistor (usually between  $5\Omega$  and  $50\Omega$ ) can be placed in series with the output to eliminate most peaking.

However, this will obviously reduce the gain slightly. If your gain is greater than 1, the gain resistor ( $R_G$ ) can then be chosen to make up for any gain loss, which may be created by this additional resistor at the output. Another method of reducing peaking is to add a “snubber” circuit at the output. A snubber is a resistor in a series with a capacitor,  $150\Omega$  and 100pF being typical values. The advantage of a snubber is that it does not draw DC load current.

When used as a cable driver, double termination is always recommended for reflection-free performance. For those applications, the back-termination series resistor will de-couple the EL5144 series amplifier from the cable and allow extensive capacitive drive. However, other applications may have high capacitive loads without a back-termination resistor. Again, a small series resistor at the output can reduce peaking.

### Disable/Power-Down

The EL5146 and EL5246 amplifiers can be disabled, placing its output in a high-impedance state. Turn-off time is only 10ns and turn-on time is around 500ns. When disabled, the amplifier's supply current is reduced to  $2.6\mu A$  typically, thereby effectively eliminating power consumption. The amplifier's power-down can be controlled by standard TTL or CMOS signal levels at the CE pin. The applied logic signal is relative to the GND pin. Letting the CE pin float will enable the amplifier. Hence, the 8 Ld PDIP and 8 Ld SOIC single amps are pin compatible with standard amplifiers that don't have a power-down feature.

### Short Circuit Current Limit

The EL5144 series amplifiers do not have internal short circuit protection circuitry. Short circuit current of 90mA sourcing and 65mA sinking typically will flow if the output is trying to drive high or low but is shorted to half way between the rails. If an output is shorted indefinitely, the power dissipation could easily increase such that the part will be destroyed. Maximum reliability is maintained if the output current never exceeds  $\pm 50mA$ . This limit is set by internal metal interconnect limitations. Obviously, short circuit conditions must not remain or the internal metal connections will be destroyed.

### Power Dissipation

With the high output drive capability of the EL5144 series amplifiers, it is possible to exceed the  $+150^\circ C$  Absolute Maximum junction temperature under certain load current conditions. Therefore, it is important to calculate the maximum junction temperature for the application to determine if load conditions or package type need to be modified for the amplifier to remain in the safe operating area.

The maximum power dissipation allowed in a package is determined according to Equation 1:

$$PD_{MAX} = \frac{T_{JMAX} - T_{AMAX}}{\theta_{JA}} \quad (EQ. 1)$$

where:

$T_{JMAX}$  = Maximum junction temperature

$T_{AMAX}$  = Maximum ambient temperature

$\theta_{JA}$  = Thermal resistance of the package

$PD_{MAX}$  = Maximum power dissipation in the package

The maximum power dissipation actually produced by an IC is the total quiescent supply current times the total power supply voltage, plus the power in the IC due to the load, or as expressed in Equation 2:

$$D_{MAX} = N \times \left[ V_S \times I_{SMAX} + (V_S - V_{OUT}) \times \frac{V_{OUT}}{R_L} \right] \quad (EQ. 2)$$

where:

N = Number of amplifiers in the package

$V_S$  = Total supply voltage

$I_{SMAX}$  = Maximum supply current per amplifier

$V_{OUT}$  = Maximum output voltage of the application

$R_L$  = Load resistance tied to ground

If we set the two  $PD_{MAX}$  equations equal to each other, we can solve for  $R_L$  using Equation 3:

$$R_L = \frac{V_{OUT} \times (V_S - V_{OUT})}{\left( \frac{T_{JMAX} - T_{AMAX}}{N \times \theta_{JA}} \right) - (V_S \times I_{SMAX})} \quad (EQ. 3)$$

Assuming worst case conditions of  $T_A = +85^\circ\text{C}$ ,  $V_{OUT} = V_S/2V$ ,  $V_S = 5.5V$ , and  $I_{SMAX} = 8.8\text{mA}$  per amplifier, following is a table of all packages and the minimum  $R_L$  allowed.

PART	PACKAGE	MINIMUM $R_L$
EL5144CW	SOT23-5	37
EL5146CS	SOIC-8	21
EL5146CN	PDIP-8	14
EL5244CS	SOIC-8	48
EL5244CN	PDIP-8	30
EL5244CY	MSOP-8	69
EL5246CY	MSOP-10	69
EL5246CS	SOIC-14	34
EL5246CN	PDIP-14	23
EL5444CU	QSOP-16	139
EL5444CS	SOIC-14	85
EL5444CN	PDIP-14	51

### EL5144 Series Comparator Application

The EL5144 series amplifier can be used as a very fast, single supply comparator. Most op amps used as a comparator allow only slow speed operation because of output saturation issues. The EL5144 series amplifier doesn't suffer from output saturation issues. Figure 50 shows the amplifier implemented as a comparator. Figure 51 is a graph of propagation delay vs overdrive as a square wave is presented at the input of the comparator.

FIGURE 50. EL5146 AMPLIFIER IMPLEMENTED AS A COMPARATOR

FIGURE 51. PROPAGATION DELAY vs OVERDRIVE FOR AMPLIFIER USED AS A COMPARATOR

### Multiplexing with the EL5144 Series Amplifier

Besides normal power-down usage, the CE pin on the EL5146 and EL5246 series amplifiers also allow for multiplexing applications. Figure 52 shows an EL5246 with its outputs tied together, driving a back terminated 75Ω video load. A 3V<sub>p-p</sub> 10MHz sine wave is applied at Amp A input, and a 2.4V<sub>p-p</sub> 5MHz square wave to Amp B. Figure 53 shows the SELECT signal that is applied, and the resulting output waveform at  $V_{OUT}$ . Observe the break-before-make operation of the multiplexing. Amp A is on and  $V_{IN1}$  is being passed through to the output of the amplifier. Then Amp A turns off in about 10ns. The output decays to ground with an  $R_L C_L$  time constants. 500ns later, Amp B turns on and  $V_{IN2}$  is passed through to the output. This break-before-make operation ensures that more than one amplifier isn't trying to drive the bus at the same time. Notice the outputs are tied directly together. Isolation resistors at each output are not necessary.

FIGURE 56.

**Free Running Oscillator Application**

Figure 54 is an EL5144 configured as a free running oscillator. To first order,  $R_{OSC}$  and  $C_{OSC}$  determine the frequency of oscillation according to:

$$F_{OSC} = \frac{0.72}{R_{OSC} \times C_{OSC}} \quad (EQ. 4)$$

For rail to rail output swings, maximum frequency of oscillation is around 15MHz. If reduced output swings are acceptable, 25MHz can be achieved. Figure 55 shows the oscillator for  $R_{OSC} = 510\Omega$ ,  $C_{OSC} = 240pF$  and  $F_{OSC} = 6MHz$ .
