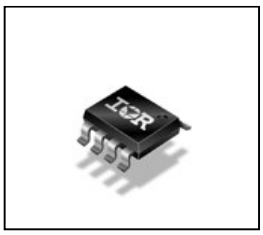
AUIR3242S

LOW QUIESCENT CURRENT BACK TO BACK MOSFET DRIVER

Features



- Very low quiescent current on and off state
- Back to back configuration
- Boost converter with integrated diode
- Standard level gate voltage
- Input active low
- Under voltage lockout with diagnostic
- Wide operating voltage 3-36V
- Ground loss protection
- Lead-Free, Halogen Free, RoHS compliant

Potential applications

- Power switch for Stop and Start board net stabilizer
- Battery switch

Description

The AUIR3242S is a high side MOSFET driver for back to back topology targeting back to back switch. It features a very low quiescent current both on and off state. The AUIR3242S is a combination of a boost DC/DC converter using an external inductor and a gate driver. It drives standard level MOSFET even at low battery voltage. The input controls the gate voltage. The AUIR3242S integrates an under voltage lock out protection to prevent to drive the MOSFET in linear mode.

7 Switching Characteristics

Tj=-40..125°C, Vcc=6..16V (unless otherwise specified), typical value are given for Vcc=14V and Tj=25°C.

Table 7 Switching characteristics

Symbol	Parameter	Min.	Typ.	Max.	Units	Test condition
Tdon gate	Turn-on delay	0.5	2	5	µs	
Tr gate	Rise time on gate 10% to 90% of Vout-Vcc	—	6	15		Cgate=100nF
Igate+	Gate high short circuit pulsed current	100	350	—	mA	Vgate-Vsource=0V
Tdoff gate	Turn-off delay	0.5	1.5	3	µs	
Tf gate	Fall time on gate 90% to 10% of Vout-Vcc	—	6	15		Cgate=100nF
Igate-	Gate low short circuit pulsed current	100	350	—	mA	Vgate-Vsource=14V
Treset	Time to reset the under voltage latches	—	1	100	µs	See page 13

8 General Description

8.1 Boost DC/DC converter

The topology of the AUIR3242S is a boost DC/DC converter working in current mode. The DC/DC is working once the AUIR3242S is powered regardless the input level.
K1 is switched on when the gate voltage is lower than Vout threshold. When Rs pin reaches Vrs th, K1 is turned off and the inductor charges the Out capacitor through D. The system cannot restart during Toff after Vrs th has been reached. The DC/DC restart only when the Out and the Vcc voltage difference is lower than Vout_th in order to achieve low quiescent current on the power supply.
To turn off the power MOSFET, the input must be low. Then K2 is turned off and K3 shorts the gate to the source.

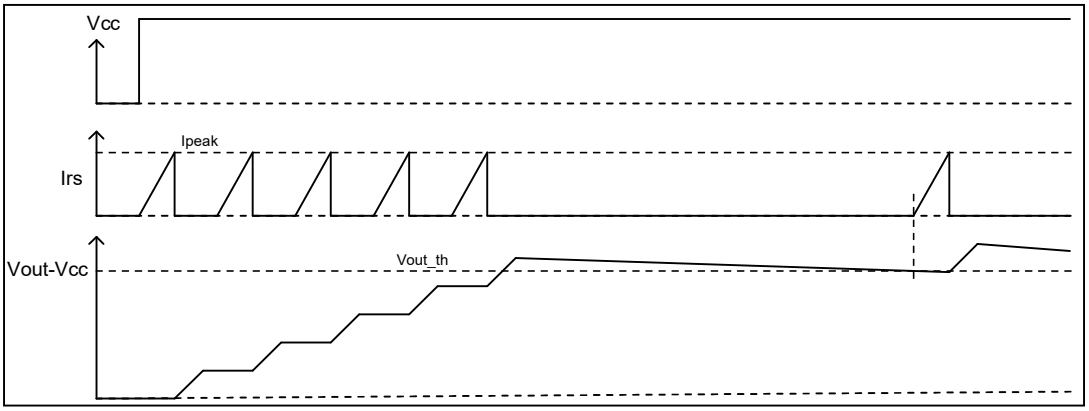

Figure 10

8.2 Low quiescent current operation when “On”.

The AUIR3242S is able to operate with a very low quiescent current on the Vcc pin. Nevertheless the supply current depends also on the leakage of the power MOSFET named “Iq gate” on the diagram below.
The leakage current is given when K1 is off. When K1 is on, the current flowing in Vcc is the current charging the inductor. Therefore the average current on the Vcc is the combination of the current when K1 is ON and OFF. The average current on the Vcc pin can be calculated using:

$$\text{I Vcc average on} = (\text{Iq gate} + \text{Iq Out On}) * \frac{\text{Vout} - \text{Vcc} + \text{Vf}}{\text{Vcc}} + \text{Iq Vcc on} + \text{Iq Out on}$$

$$\text{I Vcc average off} = (\text{Iq gate} + \text{Iq Out Off}) * \frac{\text{Vout} - \text{Vcc} + \text{Vf}}{\text{Vcc}} + \text{Iq Vcc off} + \text{Iq Out off}$$

With Vout: the average voltage on the output.
$\text{Vout average} = (\text{Vout peak} + \text{Vout th})/2$

Vout peak can be calculated by:

$$\text{Vout peak} = \sqrt{\frac{\text{L}}{\text{Cout}}.\text{Ipeak}^2 + \text{Vout th}^2}$$

During On operation, the DC/DC works in pulse mode, meaning each time the Vout-Vcc voltage comes below 12.5V, the AUIR3242S switches on K1 to recharge the gate voltage. When the Iout leakage is low enough to maintain the DC/DC in discontinuous mode, the frequency is calculate by:

$$T = \frac{Ipeak^2 * L}{2*(Iq\ gate + Iq\ Vout\ on)*(Vout - Vcc + Vf)}$$

8.3 Peak current control

The current in the inductor is limited by the 1V comparator which monitors the voltage across Rs. Due to the delay in the loop (tdoff K1), the inductor current will exceed the threshold set by: $\frac{Vrsth}{Rs}$
At low voltage, the current waveform in the inductor is not anymore linear, but exponential because the sum of the resistor of K1, the inductor and RS are not any more negligible.

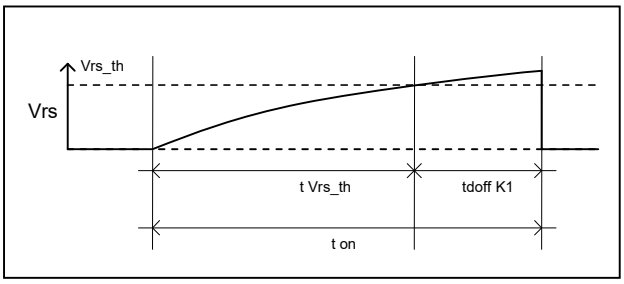

Figure 11

The peak current and ton can be calculated as follow:

$$t\ Vrsth = -\frac{L}{Rdon\ k1 + Rs + Rl} * \ln\left(1 - \frac{Rs + Rdson\ k1 + Rl}{Vrs_th * Rs * Vcc}\right)$$

Where Rl is the resistor of the inductor

With: $t\ on = t\ Vrs_th + tdoff\ K1$

The peak current can be solved by:

$$Ipeak = \frac{Vcc}{Rdson\ k1 + Rs + Rl} * \left(1 - e^{-ton * \frac{Rdson\ k1 + Rs + Rl}{L}}\right)$$

The peak current must not exceed the Maximum Rating of Isw.

8.4 Output capacitor choice

The output capacitor must be chosen based on 2 criteria:

- During the turn on of K2, the voltage drop on Cout must not trigger the Under Voltage Lockout due to the gate charge of the Power MOSFET

$$\text{Cout} > \frac{\text{Q gate total Power Mosfet}}{(\text{Vout}_{\text{th}} - \text{UV}_{\text{LO}})\ \text{Min.}}$$

- When K1 turn off and the inductor is charging Cout, the peak current on the output capacitor must be limited in order to avoid having current flowing in the Gate zener diode:

$$\text{Cout} > \frac{\text{L} * \text{Ipeak}^2\text{max}}{\text{Vz min gate}^{\,2} - \text{Vout th max}^2}$$

Vz min gate is the minimum Zener voltage of the external gate Zener diode.

8.5 Minimum operating voltage

While the AUIR3242S operating voltage is specified between 3V and 36V. The 3V minimum operating voltage is when the Vcc is going down. The minimum voltage is also limited by the fact that the Rs voltage must reach the Vrsth taking account all resistors which limit the inductor current.

$$\text{Vcc min} = \frac{\text{Rdson k1} + \text{Rs} + \text{Rl}}{\text{Rs}} * \text{Vrsth}$$

8.6 Over-Voltage protection

The AUIR3242S integrates an over-voltage protection in order to protect K1. When Vcc exceed the Over-voltage threshold, the DC/DC is stopped.

8.7 Under voltage lockout - Diagnostic

In order to avoid to drive the Power MOSFET in linear mode, the AUIR3242S features an under voltage lockout. During the turn on, the gate will not be powered until Vout-Vcc reaches Vout th, meaning K2 is off and K3 is on. Then the AUIR3242S powers the gate of the MOSFET. If Vout-Vcc goes below UV_LO, the gate is shorted to the source and the part is latched. A cycle in the input is required to reset the latch. The input must be kept low longer than Treset.

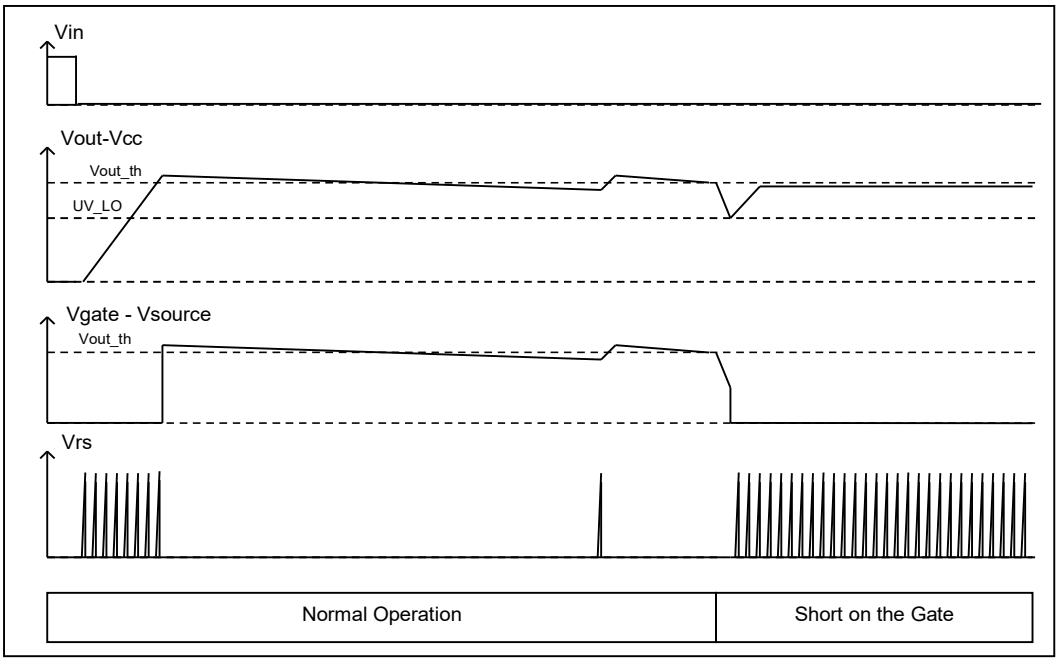

Figure 12

When the part is latched a current source (I latch UV_LO) is connected between Out and Vcc to increase the current consumption. By monitoring the current consumption the system can have a diagnostic of the output status. The diagnostic can be analog or digital.

8.8 Analog Diagnostic: Output current measurement

The average current into Rs can be measured by adding a low pass filter before the ADC of the micro controller.

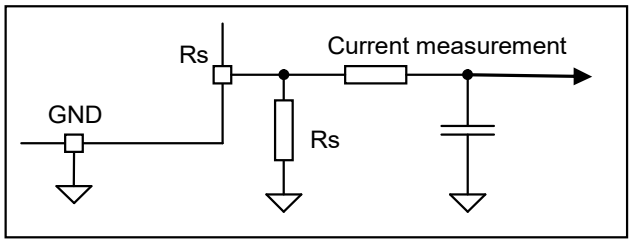

Figure 13

Then the average output current can be evaluated using:
I out av = I Rs av * Vcc / (Vout - Vcc)
Knowing the output current can be useful to do a diagnostic on the power MOSFET. If the gate is shorted, the output current will be significantly higher than in normal operation.

8.9 Digital diagnostic

By adding a diode during high current consumption mode, the output voltage can be close to 1V. Using a bipolar with a pull-up resistor will provide a digital diagnostic.

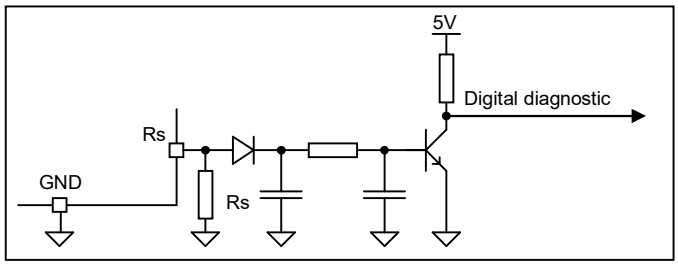

Figure 14

8.10 Power On Reset

During the power on, the AUIR3242S features a Power On Reset to guarantee a stable state of the 2 latches of the Under voltage lockout and guarantee a stable internal biasing. POR_Delay is triggered when Vout-Gnd exceeds POR_Th.

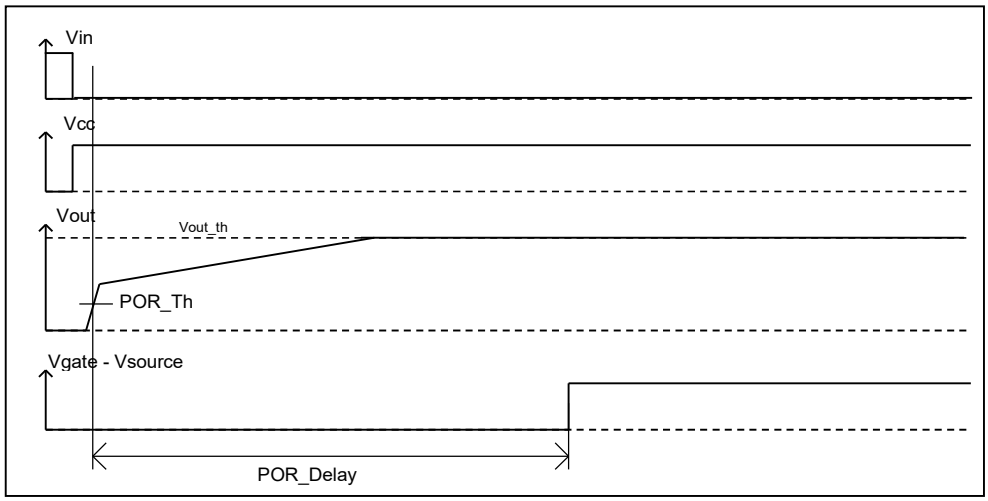

Figure 15
