

# TigerSHARC® Embedded Processor

# ADSP-TS202S

#### **KEY FEATURES**

- **500 MHz, 2.0 ns instruction cycle rate**
- **12M bits of internal—on-chip—DRAM memory**
- **25 mm × 25 mm (576-ball) thermally enhanced ball grid array package**
- **Dual-computation blocks—each containing an ALU, a multiplier, a shifter, and a register file**
- **Dual-integer ALUs, providing data addressing and pointer manipulation**
- **Single-precision IEEE 32-bit and extended-precision 40-bit floating-point data formats and 8-, 16-, 32-, and 64-bit fixed-point data formats**
- **Integrated I/O includes 14-channel DMA controller, external port, four link ports, SDRAM controller, programmable flag pins, two timers, and timer expired pin for system integration**
- **1149.1 IEEE-compliant JTAG test access port for on-chip emulation**
- **On-chip arbitration for glueless multiprocessing**

#### **KEY BENEFITS**

- **Provides high performance static superscalar DSP operations, optimized for large, demanding multiprocessor DSP applications**
- **Performs exceptionally well on DSP algorithm and I/O benchmarks (see benchmarks in Table 1)**
- **Supports low overhead DMA transfers between internal memory, external memory, memory-mapped peripherals, link ports, host processors, and other (multiprocessor) DSPs**
- **Eases programming through extremely flexible instruction set and high-level-language-friendly DSP architecture Enables scalable multiprocessing systems with low**

**communications overhead**

## <span id="page-2-1"></span>GENERAL DESCRIPTION

The ADSP-TS202S TigerSHARC processor is an ultrahigh performance, static superscalar processor optimized for large signal processing tasks and communications infrastructure. The DSP combines very wide memory widths with dual computation blocks—supporting floating-point (IEEE 32-bit and extended precision 40-bit) and fixed-point (8-, 16-, 32-, and 64-bit) processing—to set a new standard of performance for digital signal processors. The TigerSHARC static superscalar architecture lets the DSP execute up to four instructions each cycle, performing 24 fixed-point (16-bit) operations or six floating-point operations.

Four independent 128-bit wide internal data buses, each connecting to the six 2M bit memory banks, enable quad-word data, instruction, and I/O accesses and provide 28G bytes per second of internal memory bandwidth. Operating at 500 MHz, the ADSP-TS202S processor's core has a 2.0 ns instruction cycle time. Using its single-instruction, multiple-data (SIMD) features, the ADSP-TS202S processor can perform four billion 40-bit MACS or one billion 80-bit MACS per second. Table 1 shows the DSP's performance benchmarks.

#### <span id="page-2-0"></span>**Table 1. General-Purpose Algorithm Benchmarks at 500 MHz**

<span id="page-2-2"></span><sup>1</sup> Cache preloaded.

The ADSP-TS202S processor is code-compatible with the other TigerSHARC processors.

The Functional Block Diagram [on Page 1](#page-0-0) shows the ADSP-TS202S processor's architectural blocks. These blocks include

- Dual compute blocks, each consisting of an ALU, multiplier, 64-bit shifter, and 32-word register file and associated data alignment buffers (DABs)
- Dual integer ALUs (IALUs), each with its own 31-word register file for data addressing and a status register
- A program sequencer with instruction alignment buffer (IAB) and branch target buffer (BTB)
- An interrupt controller that supports hardware and software interrupts, supports level- or edge-triggers, and supports prioritized, nested interrupts
- Four 128-bit internal data buses, each connecting to the six 2M-bit memory banks
- On-chip DRAM (12M-bit)
- An external port that provides the interface to host processors, multiprocessing space (DSPs), off-chip memorymapped peripherals, and external SRAM and SDRAM
- A 14-channel DMA controller
- Four full-duplex LVDS link ports
- Two 64-bit interval timers and timer expired pin
- An 1149.1 IEEE compliant JTAG test access port for onchip emulation

Figure 2 shows a typical single-processor system with external SRAM and SDRAM. Figure 4 on Page 8 shows a typical multiprocessor system.

<span id="page-2-3"></span>Figure 2. ADSP-TS202S Single-Processor System with External SDRAM

The TigerSHARC DSP uses a Static Superscalar $^{\text{TM}}$  architecture. This architecture is superscalar in that the ADSP-TS202S processor's core can execute simultaneously from one to four 32-bit instructions encoded in a very large instruction word (VLIW) instruction line using the DSP's dual compute blocks. Because the DSP does not perform instruction reordering at runtime the programmer selects which operations will execute in parallel prior to runtime—the order of instructions is static.

With few exceptions, an instruction line, whether it contains one, two, three, or four 32-bit instructions, executes with a throughput of one cycle in a 10-deep processor pipeline.

For optimal DSP program execution, programmers must follow the DSP's set of instruction parallelism rules when encoding an instruction line. In general, the selection of parallel instructions that the DSP can execute in each cycle depends on both the instruction line resources each instruction requires and on the source and destination registers used in the instructions. The programmer has direct control of three core components—the IALUs, the compute blocks, and the program sequencer.

The ADSP-TS202S processor, in most cases, has a two-cycle execution pipeline that is fully interlocked, so—whenever a computation result is unavailable for another operation dependent on it—the DSP automatically inserts one or more stall cycles as needed. Efficient programming with dependency-free instructions can eliminate most computational and memory transfer data dependencies.

In addition, the ADSP-TS202S processor supports SIMD operations two ways—SIMD compute blocks and SIMD computations. The programmer can load both compute blocks with the same data (broadcast distribution) or different data (merged distribution).

## <span id="page-3-0"></span>**DUAL COMPUTE BLOCKS**

The ADSP-TS202S processor has compute blocks that can execute computations either independently or together as a single-instruction, multiple-data (SIMD) engine. The DSP can issue up to two compute instructions per compute block each cycle, instructing the ALU, multiplier, or shifter to perform independent, simultaneous operations. Each compute block can execute eight 8-bit, four 16-bit, two 32-bit, or one 64-bit SIMD computations in parallel with the operation in the other block. These computation units support IEEE 32-bit single-precision floating-point, extended-precision 40-bit floating point, and 8-, 16-, 32-, and 64-bit fixed-point processing. Cycle in a 10-dependent of the positive of the matter of the state of the state of the cycle in a margin distinguished and two states of the matter of the state of the st

The compute blocks are referred to as X and Y in assembly syntax, and each block contains three computational units—an ALU, a multiplier, and a 64-bit shifter—and a 32-word register file.

• Register File—each compute block has a multiported, 32-word, fully orthogonal register file used for transferring data between the computation units and data buses and for

storing intermediate results. Instructions can access the registers in the register file individually (word-aligned), in sets of two (dual-aligned), or in sets of four (quad-aligned).

- ALU—the ALU performs a standard set of arithmetic operations in both fixed- and floating-point formats. It also performs logic and permute operations.
- Multiplier—the multiplier performs both fixed- and floating-point multiplication and fixed-point multiply and accumulate.
- Shifter—the 64-bit shifter performs logical and arithmetic shifts, bit and bit stream manipulation, and field deposit and extraction operations.

Using these features, the compute blocks can

- Provide 8 MACS per cycle peak and 7.1 MACS per cycle sustained 16-bit performance and provide 2 MACS per cycle peak and 1.8 MACS per cycle sustained 32-bit performance (based on FIR)
- Execute six single-precision floating-point or execute 24 fixed-point (16-bit) operations per cycle, providing 3G FLOPS or 12.0G/s regular operations performance at 500 MHz
- Perform two complex 16-bit MACS per cycle

## <span id="page-3-1"></span>**DATA ALIGNMENT BUFFER (DAB)**

The DAB is a quad-word FIFO that enables loading of quadword data from nonaligned addresses. Normally, load instructions must be aligned to their data size so that quad words are loaded from a quad-aligned address. Using the DAB significantly improves the efficiency of some applications, such as FIR filters.

## <span id="page-3-2"></span>**DUAL INTEGER ALU (IALU)**

The ADSP-TS202S processor has two IALUs that provide powerful address generation capabilities and perform many generalpurpose integer operations. The IALUs are referred to as J and K in assembly syntax and have the following features:

- Provide memory addresses for data and update pointers
- Support circular buffering and bit-reverse addressing
- Perform general-purpose integer operations, increasing programming flexibility
- Include a 31-word register file for each IALU

As address generators, the IALUs perform immediate or indirect (pre- and post-modify) addressing. They perform modulus and bit-reverse operations with no constraints placed on memory addresses for the modulus data buffer placement. Each IALU can specify either a single-, dual-, or quad-word access from memory.

The IALUs have hardware support for circular buffers, bit reverse, and zero-overhead looping. Circular buffers facilitate efficient programming of delay lines and other data structures required in digital signal processing, and they are commonly used in digital filters and Fourier transforms. Each IALU provides registers for four circular buffers, so applications can set

<sup>†</sup> Static Superscalar is a trademark of Analog Devices, Inc.

up a total of eight circular buffers. The IALUs handle address pointer wraparound automatically, reducing overhead, increasing performance, and simplifying implementation. Circular buffers can start and end at any memory location.

Because the IALU's computational pipeline is one cycle deep, in most cases integer results are available in the next cycle. Hardware (register dependency check) causes a stall if a result is unavailable in a given cycle.

## <span id="page-4-0"></span>**PROGRAM SEQUENCER**

The ADSP-TS202S processor's program sequencer supports the following:

- A fully interruptible programming model with flexible programming in assembly and C/C++ languages; handles hardware interrupts with high throughput and no aborted instruction cycles
- A 10-cycle instruction pipeline—four-cycle fetch pipe and six-cycle execution pipe—computation results available two cycles after operands are available
- Supply of instruction fetch memory addresses; the sequencer's instruction alignment buffer (IAB) caches up to five fetched instruction lines waiting to execute; the program sequencer extracts an instruction line from the IAB and distributes it to the appropriate core component for execution
- Management of program structures and program flow determined according to JUMP, CALL, RTI, RTS instructions, loop structures, conditions, interrupts, and software exceptions
- Branch prediction and a 128-entry branch target buffer (BTB) to reduce branch delays for efficient execution of conditional and unconditional branch instructions and zero-overhead looping; correctly predicted branches that are taken occur with zero overhead cycles, overcoming the five-to-nine stage branch penalty
- Compact code without the requirement to align code in memory; the IAB handles alignment

#### <span id="page-4-1"></span>**Interrupt Controller**

The DSP supports nested and nonnested interrupts. Each interrupt type has a register in the interrupt vector table. Also, each has a bit in both the interrupt latch register and the interrupt mask register. All interrupts are fixed as either level-sensitive or edge-sensitive, except the  $\overline{\text{IRQ3}-0}$  hardware interrupts, which are programmable.

The DSP distinguishes between hardware interrupts and software exceptions, handling them differently. When a software exception occurs, the DSP aborts all other instructions in the instruction pipe. When a hardware interrupt occurs, the DSP continues to execute instructions already in the instruction pipe.

#### <span id="page-4-2"></span>**Flexible Instruction Set**

The 128-bit instruction line, which can contain up to four 32-bit instructions, accommodates a variety of parallel operations for concise programming. For example, one instruction line can

direct the DSP to conditionally execute a multiply, an add, and a subtract in both computation blocks while it also branches to another location in the program. Some key features of the instruction set include

- Algebraic assembly language syntax
- Direct support for all DSP, imaging, and video arithmetic types
- Eliminates toggling DSP hardware modes because modes are supported as options (for example, rounding, saturation, and others) within instructions
- Branch prediction encoded in instruction; enables zerooverhead loops
- Parallelism encoded in instruction line
- Conditional execution optional for all instructions
- User-defined partitioning between program and data memory

## <span id="page-4-3"></span>**DSP MEMORY**

The DSP's internal and external memory is organized into a unified memory map, which defines the location (address) of all elements in the system, as shown in Figure 3.

The memory map is divided into four memory areas—host space, external memory, multiprocessor space, and internal memory—and each memory space, except host memory, is subdivided into smaller memory spaces.

The ADSP-TS202S processor internal memory has 12M bits of on-chip DRAM memory, divided into six blocks of 2M bits  $(64K$  words  $\times$  32 bits). Each block—M0, M2, M4, M6, M8, and M10—can store program instructions, data, or both, so applications can configure memory to suit specific needs. Placing program instructions and data in different memory blocks, however, enables the DSP to access data while performing an instruction fetch. Each memory segment contains a 128K bit cache to enable single-cycle accesses to internal DRAM. 2025 processor's program sequencer supports the<br>
wave and ordering model with decision encoded in instruction<br>
is in assembly and CC++ languages; handles provided in instruction<br>
in the interruption worthead loops<br>
in a se

The six internal memory blocks connect to the four 128-bit wide internal buses through a crossbar connection, enabling the DSP to perform four memory transfers in the same cycle. The DSP's internal bus architecture provides a total memory bandwidth of 28G bytes per second, enabling the core and I/O to access eight 32-bit data-words and four 32-bit instructions each cycle. The DSP's flexible memory structure enables

- DSP core and I/O accesses to different memory blocks in the same cycle
- DSP core access to three memory blocks in parallel—one instruction and two data accesses
- Programmable partitioning of program and data memory
- Program access of all memory as 32-, 64-, or 128-bit words—16-bit words with the DAB

Figure 3. ADSP-TS202S Memory Map

## <span id="page-5-2"></span><span id="page-5-0"></span>**EXTERNAL PORT (OFF-CHIP MEMORY/PERIPHERALS INTERFACE)**

The ADSP-TS202S processor's external port provides the DSP's interface to off-chip memory and peripherals. The 4G word address space is included in the DSP's unified address space. The separate on-chip buses—four 128-bit data buses and four 32-bit address buses—are multiplexed at the SOC interface and transferred to the external port over the SOC bus to create an external system bus transaction. The external system bus provides a single 64-bit data bus and a single 32-bit address bus. The external port supports data transfer rates of 1G bytes per second over the external bus.

The external bus can be configured for 32-bit or 64-bit, littleendian operations. When the system bus is configured for 64-bit operations, the lower 32 bits of the external data bus connect to even addresses, and the upper 32 bits connect to odd addresses.

The external port supports pipelined, slow, and SDRAM protocols. Addressing of external memory devices and memorymapped peripherals is facilitated by on-chip decoding of high order address lines to generate memory bank select signals.

The ADSP-TS202S processor provides programmable memory, pipeline depth, and idle cycle for synchronous accesses, and external acknowledge controls to support interfacing to pipelined or slow devices, host processors, and other memorymapped peripherals with variable access, hold, and disable time requirements.

#### <span id="page-5-1"></span>**Host Interface**

The ADSP-TS202S processor provides an easy and configurable interface between its external bus and host processors through the external port. To accommodate a variety of host processors, the host interface supports pipelined or slow protocols for

ADSP-TS202S processor accesses of the host as slave or pipelined for host accesses of the ADSP-TS202S processor as slave. Each protocol has programmable transmission parameters, such as idle cycles, pipe depth, and internal wait cycles.

The host interface supports burst transactions initiated by a host processor. After the host issues the starting address of the burst and asserts the BRST signal, the DSP increments the address internally while the host continues to assert BRST.

The host interface provides a deadlock recovery mechanism that enables a host to recover from deadlock situations involving the DSP. The BOFF signal provides the deadlock recovery mechanism. When the host asserts BOFF, the DSP backs off the current transaction and asserts HBG and relinquishes the external bus.

The host can directly read or write the internal memory of the ADSP-TS202S processor, and it can access most of the DSP registers, including DMA control (TCB) registers. Vector interrupts support efficient execution of host commands.

#### <span id="page-6-0"></span>**Multiprocessor Interface**

The ADSP-TS202S processor offers powerful features tailored to multiprocessing DSP systems through the external port and link ports. This multiprocessing capability provides highest bandwidth for interprocessor communication, including

- Up to eight DSPs on a common bus
- On-chip arbitration for glueless multiprocessing
- Link ports for point-to-point communication

The external port and link ports provide integrated, glueless multiprocessing support.

The external port supports a unified address space (see Figure 3) that enables direct interprocessor accesses of each ADSP-TS202S processor's internal memory and registers. The DSP's on-chip distributed bus arbitration logic provides simple, glueless connection for systems containing up to eight ADSP-TS202S processors and a host processor. Bus arbitration has a rotating priority. Bus lock supports indivisible readmodify-write sequences for semaphores. A bus fairness feature prevents one DSP from holding the external bus too long. Fraginal provides the dealedoch recovery mechanical the heating Fraginal provides the conservation of the term of the term of the species of the DSP sumiford more principle and the small term of the SP sumiform of the SP

The DSP's four link ports provide a second path for interprocessor communications with throughput of 4G bytes per second. The cluster bus provides 1G bytes per second throughput—with a total of 4G bytes per second interprocessor bandwidth (limited by SOC bandwidth).

#### <span id="page-6-1"></span>**SDRAM Controller**

The SDRAM controller controls the ADSP-TS202S processor's transfers of data to and from external synchronous DRAM (SDRAM) at a throughput of 32 bits or 64 bits per SCLK cycle using the external port and SDRAM control pins.

The SDRAM interface provides a glueless interface with standard SDRAMs—16M bits, 64M bits, 128M bits, 256M bits, and 512M bits. The DSP supports directly a maximum of four banks of 64M words × 32 bits of SDRAM. The SDRAM interface is mapped in external memory in each DSP's unified memory map.

#### <span id="page-6-2"></span>**EPROM Interface**

The ADSP-TS202S processor can be configured to boot from an external 8-bit EPROM at reset through the external port. An automatic process (which follows reset) loads a program from the EPROM into internal memory. This process uses 16 wait cycles for each read access. During booting, the BMS pin functions as the EPROM chip select signal. The EPROM boot procedure uses DMA Channel 0, which packs the bytes into 32-bit instructions. Applications can also access the EPROM (write flash memories) during normal operation through DMA.

The EPROM or flash memory interface is not mapped in the DSP's unified memory map. It is a byte address space limited to a maximum of 16M bytes (24 address bits). The EPROM or flash memory interface can be used after boot via a DMA.

## <span id="page-6-3"></span>**DMA CONTROLLER**

The ADSP-TS202S processor's on-chip DMA controller, with 14 DMA channels, provides zero-overhead data transfers without processor intervention. The DMA controller operates independently and invisibly to the DSP's core, enabling DMA operations to occur while the DSP's core continues to execute program instructions.

The DMA controller performs DMA transfers between internal memory and external memory and memory-mapped peripherals, the internal memory of other DSPs on a common bus, a host processor, or link port I/O; between external memory and external peripherals or link port I/O; and between an external bus master and internal memory or link port I/O. The DMA controller performs the following DMA operations:

- External port block transfers. Four dedicated bidirectional DMA channels transfer blocks of data between the DSP's internal memory and any external memory or memorymapped peripheral on the external bus. These transfers support master mode and handshake mode protocols.
- Link port transfers. Eight dedicated DMA channels (four transmit and four receive) transfer quad-word data only between link ports and between a link port and internal or external memory. These transfers only use handshake mode protocol. DMA priority rotates between the four receive channels.
- AutoDMA transfers. Two dedicated unidirectional DMA channels transfer data received from an external bus master to internal memory or link port I/O. These transfers only use slave mode protocol, and an external bus master must initiate the transfer.

The DMA controller provides these additional features:

• Flyby transfers. Flyby operations only occur through the external port (DMA channel 0) and do not involve the DSP's core. The DMA controller acts as a conduit to transfer data from an external I/O device and external SDRAM memory. During a transaction, the DSP relinquishes the

Figure 4. ADSP-TS202S Shared Memory Multiprocessing System

<span id="page-7-0"></span>external data bus; outputs addresses and memory selects (MSSD3–0); outputs the IORD, IOWR, IOEN, and RD/WR strobes; and responds to ACK.

- DMA chaining. DMA chaining operations enable applications to automatically link one DMA transfer sequence to another for continuous transmission. The sequences can occur over different DMA channels and have different transmission attributes.
- Two-dimensional transfers. The DMA controller can access and transfer two-dimensional memory arrays on any DMA transmit or receive channel. These transfers are implemented with index, count, and modify registers for both the X and Y dimensions.

### <span id="page-8-0"></span>**LINK PORTS (LVDS)**

The DSP's four full-duplex link ports each provide additional four-bit receive and four-bit transmit I/O capability, using low voltage, differential-signal (LVDS) technology. With the ability to operate at a double data rate—latching data on both the rising and falling edges of the clock—running at 500 MHz, each link port can support up to 500M bytes per second per direction, for a combined maximum throughput of 4G bytes per second.

The link ports provide an optional communications channel that is useful in multiprocessor systems for implementing pointto-point interprocessor communications. Applications can also use the link ports for booting.

Each link port has its own triple-buffered quad-word input and double-buffered quad-word output registers. The DSP's core can write directly to a link port's transmit register and read from a receive register, or the DMA controller can perform DMA transfers through eight (four transmit and four receive) dedicated link port DMA channels.

Each link port direction has three signals that control its operation. For the transmitter, LxCLKOUT is the output transmit clock, LxACKI is the handshake input to control the data flow, and the LxBCMPO output indicates that the block transfer is complete. For the receiver, LxCLKIN is the input receive clock, LxACKO is the handshake output to control the data flow, and the LxBCMPI input indicates that the block transfer is complete. The LxDATO3–0 pins are the data output bus for the transmitter and the LxDATI3–0 pins are the input data bus for the receiver.

Applications can program separate error detection mechanisms for transmit and receive operations (applications can use the checksum mechanism to implement consecutive link port transfers), the size of data packets, and the speed at which bytes are transmitted.

## <span id="page-8-1"></span>**TIMER AND GENERAL-PURPOSE I/O**

The ADSP-TS202S processor has a timer pin (TMR0E) that generates output when a programmed timer counter has expired and four programmable general-purpose I/O pins (FLAG3–0) that can function as either single-bit input or output. As outputs, these pins can signal peripheral devices; as inputs, they can provide the test for conditional branching.

### <span id="page-8-2"></span>**RESET AND BOOTING**

The ADSP-TS202S processor has three levels of reset:

- Power-up reset—after power-up of the system (SCLK, all static inputs, and strap pins are stable), the RST\_IN pin must be asserted (low).
- Normal reset—for any chip reset following the power-up reset, the RST\_IN pin must be asserted (low).
- DSP-core reset—when setting the SWRST bit in EMUCTL, the DSP core is reset, but not the external port or I/O.

For normal operations, tie the RST\_OUT pin to the POR\_IN pin.

After reset, the ADSP-TS202S processor has four boot options for beginning operation:

- Boot from EPROM.
- Boot by an external master (host or another ADSP-TS202S processor).
- Boot by link port.
- No boot—start running from memory address selected with one of the  $\overline{\text{IRQ3}-0}$  interrupt signals. See [Table 2](#page-8-4).

Using the "no boot" option, the ADSP-TS202S processor must start running from memory when one of the interrupts is asserted.

<span id="page-8-4"></span>

The ADSP-TS202S processor core always exits from reset in the idle state and waits for an interrupt. Some of the interrupts in the interrupt vector table are initialized and enabled after reset.

For more information on boot options, see the *EE-200: ADSP-TS20x TigerSHARC Processor Boot Loader Kernels Operation* on the Analog Devices website [\(www.analog.com\)](http://www.analog.com).

## <span id="page-8-3"></span>**CLOCK DOMAINS**

The DSP uses calculated ratios of the SCLK clock to operate as shown in Figure 5. The instruction execution rate is equal to CCLK. A PLL from SCLK generates CCLK, which is phaselocked. The SCLKRATx pins define the clock multiplication of SCLK to CCLK (see Table 4 on Page 12). The link port clock is generated from CCLK via a software programmable divisor, and the SOC bus operates at 1/2 CCLK. Memory transfers to external, and link port buffers operate at the SOCCLK rate. SCLK also provides clock input for the external bus interface and defines the ac specification reference for the external bus signals. The external bus interface runs at the SCLK frequency. The maximum SCLK frequency is one quarter the internal DSP clock (CCLK) frequency. processor communications. Applications can also<br>
orts for booting.<br>
The site of the site over the site of the site over the site over the site over the site over the site of the site of the site of the site of the site of

<span id="page-8-5"></span>Figure 5. Clock Domains

### <span id="page-9-0"></span>**POWER DOMAINS**

The ADSP-TS202S processor has separate power supply connections for internal logic ( $V_{DD}$ ), analog circuits ( $V_{DD}$ <sub>A</sub>), I/O buffer ( $V_{DDIO}$ ), and internal DRAM ( $V_{DDIDRAM}$ ) power supply.

Note that the analog ( $V_{DD_A}$ ) supply powers the clock generator PLLs. To produce a stable clock, systems must provide a clean power supply to power input  $V_{DDA}$ . Designs must pay critical attention to bypassing the  $V_{DD}$  A supply.

## <span id="page-9-1"></span>**FILTERING REFERENCE VOLTAGE AND CLOCKS**

[Figure 6](#page-9-4) and [Figure 7](#page-9-3) show possible circuits for filtering  $V_{REF}$ , and SCLK\_VREF. These circuits provide the reference voltages for the switching voltage reference and system clock reference.

#### <span id="page-9-3"></span><span id="page-9-2"></span>**DEVELOPMENT TOOLS**

The ADSP-TS202S processor is supported with a complete set of CROSSCORE<sup>®†</sup> software and hardware development tools, including Analog Devices emulators and Visual $\mathrm{DSP+}\!+\!^{\circledR \ddagger}$  development environment. The same emulator hardware that supports other TigerSHARC processors also fully emulates the ADSP-TS202S processor.

The VisualDSP++ project management environment lets programmers develop and debug an application. This environment includes an easy to use assembler (which is based on an algebraic syntax), an archiver (librarian/library builder), a linker, a loader, a cycle-accurate instruction-level simulator, a C/C++ compiler, and a C/C++ run-time library that includes DSP and mathematical functions. A key point for theses tools is C/C++ code efficiency. The compiler has been developed for efficient translation of C/C++ code to DSP assembly. The DSP has architectural features that improve the efficiency of compiled C/C++ code.

The VisualDSP++ debugger has a number of important features. Data visualization is enhanced by a plotting package that offers a significant level of flexibility. This graphical representation of user data enables the programmer to quickly determine the performance of an algorithm. As algorithms grow in complexity, this capability can have increasing significance on the designer's development schedule, increasing productivity. Statistical profiling enables the programmer to nonintrusively poll the processor as it is running the program. This feature, unique to VisualDSP++, enables the software developer to passively gather important code execution metrics without interrupting the real-time characteristics of the program. Essentially, the developer can identify bottlenecks in software quickly and efficiently. By using the profiler, the programmer can focus on those areas in the program that impact performance and take corrective action.

Debugging both C/C++ and assembly programs with the VisualDSP++ debugger, programmers can

- View mixed C/C++ and assembly code (interleaved source and object information)
- Insert breakpoints
- Set conditional breakpoints on registers, memory, and stacks
- Trace instruction execution
- Perform linear or statistical profiling of program execution
- Fill, dump, and graphically plot the contents of memory
- Perform source level debugging
- Create custom debugger windows

The VisualDSP++ IDE lets programmers define and manage DSP software development. Its dialog boxes and property pages let programmers configure and manage all of the TigerSHARC processor development tools, including the color syntax highlighting in the VisualDSP++ editor. This capability permits programmers to

- Control how the development tools process inputs and generate outputs
- Maintain a one-to-one correspondence with the tool's command line switches

The VisualDSP++ Kernel (VDK) incorporates scheduling and resource management tailored specifically to address the memory and timing constraints of DSP programming. These capabilities enable engineers to develop code more effectively,

<sup>†</sup>CROSSCORE is a registered trademark of Analog Devices, Inc.

<sup>‡</sup> VisualDSP++ is a registered trademark of Analog Devices, Inc.

eliminating the need to start from the very beginning, when developing new application code. The VDK features include threads, critical and unscheduled regions, semaphores, events, and device flags. The VDK also supports priority-based, preemptive, cooperative, and time-sliced scheduling approaches. In addition, the VDK was designed to be scalable. If the application does not use a specific feature, the support code for that feature is excluded from the target system.

Because the VDK is a library, a developer can decide whether to use it or not. The VDK is integrated into the VisualDSP++ development environment, but can also be used via standard command line tools. When the VDK is used, the development environment assists the developer with many error-prone tasks and assists in managing system resources, automating the generation of various VDK-based objects, and visualizing the system state, when debugging an application that uses the VDK.

VCSE is Analog Devices technology for creating, using, and reusing software components (independent modules of substantial functionality) to quickly and reliably assemble software applications. It also can be used for downloading components from the Web, dropping them into the application, and publishing component archives from within VisualDSP++. VCSE supports component implementation in C/C++ or assembly language.

Use the expert linker to visually manipulate the placement of code and data on the embedded system, view memory use in a color-coded graphical form, easily move code and data to different areas of the DSP or external memory with a drag of the mouse, and examine runtime stack and heap usage. The expert linker is fully compatible with existing linker definition file (LDF), allowing the developer to move between the graphical and textual environments.

Analog Devices DSP emulators use the IEEE 1149.1 JTAG test access port of the ADSP-TS202S processor to monitor and control the target board processor during emulation. The emulator provides full speed emulation, allowing inspection and modification of memory, registers, and processor stacks. Nonintrusive in-circuit emulation is assured by the use of the processor's JTAG interface—the emulator does not affect target system loading or timing.

In addition to the software and hardware development tools available from Analog Devices, third parties provide a wide range of tools supporting the TigerSHARC processor family. Hardware tools include TigerSHARC processor PC plug-in cards. Third party software tools include DSP libraries, realtime operating systems, and block diagram design tools.

## <span id="page-10-0"></span>**EVALUATION KIT**

Analog Devices offers a range of EZ-KIT Lite®<sup>†</sup> evaluation platforms to use as a cost-effective method to learn more about developing or prototyping applications with Analog Devices processors, platforms, and software tools. Each EZ-KIT Lite includes an evaluation board along with an evaluation suite of the VisualDSP++ development and debugging environment

with the C/C++ compiler, assembler, and linker. Also included are sample application programs, power supply, and a USB cable. All evaluation versions of the software tools are limited for use only with the EZ-KIT Lite product.

The USB controller on the EZ-KIT Lite board connects the board to the USB port of the user's PC, enabling the VisualDSP++ evaluation suite to emulate the on-board processor in-circuit. This permits the customer to download, execute, and debug programs for the EZ-KIT Lite system. It also allows in-circuit programming of the on-board flash device to store user-specific boot code, enabling the board to run as a standalone unit, without being connected to the PC.

With a full version of VisualDSP++ installed (sold separately), engineers can develop software for the EZ-KIT Lite or any custom-defined system. Connecting one of Analog Devices JTAG emulators to the EZ-KIT Lite board enables high speed, nonintrusive emulation.

## **DESIGNING AN EMULATOR-COMPATIBLE DSP BOARD (TARGET)**

The Analog Devices family of emulators are tools that every DSP developer needs to test and debug hardware and software systems. Analog Devices has supplied an IEEE 1149.1 JTAG test access port (TAP) on each JTAG DSP. The emulator uses the TAP to access the internal features of the DSP, allowing the developer to load code, set breakpoints, observe variables, observe memory, and examine registers. The DSP must be halted to send data and commands, but once an operation has been completed by the emulator, the DSP system is set running at full speed with no impact on system timing. environment, but can also be used van standard<br>
et cols. When the VDK is used, the development<br>

in any erro-prone taxts and the standar

To use these emulators, the target board must include a header that connects the DSP's JTAG port to the emulator.

<span id="page-10-2"></span>For details on target board design issues including mechanical layout, single processor connections, multiprocessor scan chains, signal buffering, signal termination, and emulator pod logic, see the *EE-68: Analog Devices JTAG Emulation Technical Reference* on the Analog Devices website [\(www.analog.com\)](http://www.analog.com) use the string "EE-68" in site search. This document is updated regularly to keep pace with improvements to emulator support.

## <span id="page-10-1"></span>**ADDITIONAL INFORMATION**

This data sheet provides a general overview of the ADSP-TS202S processor's architecture and functionality. For detailed information on the ADSP-TS202S processor's core architecture and instruction set, see the *ADSP-TS201 Tiger-SHARC Processor Hardware Reference* and the *ADSP-TS201 TigerSHARC Processor Programming Reference*. For detailed information on the development tools for this processor, see the *VisualDSP++ User's Guide for TigerSHARC Processors*.

## <span id="page-11-0"></span>PIN FUNCTION DESCRIPTIONS

While most of the ADSP-TS202S processor's input pins are normally synchronous—tied to a specific clock—a few are asynchronous. For these asynchronous signals, an on-chip synchronization circuit prevents metastability problems. Use the ac specification for asynchronous signals when the system design requires predictable, cycle-by-cycle behavior for these signals.

The output pins can be three-stated during normal operation. The DSP three-states all outputs during reset, allowing these pins to get to their internal pull-up or pull-down state. Some pins have an internal pull-up or pull-down resistor (±30% tolerance) that maintains a known value during transitions between different drivers.

## <span id="page-19-0"></span>STRAP PIN FUNCTION DESCRIPTIONS

Some pins have alternate functions at reset. Strap options set DSP operating modes. During reset, the DSP samples the strap option pins. Strap pins have an internal pull-up or pull-down for the default value. If a strap pin is not connected to an overdriving external pull-up, pull-down, or logic load, the DSP samples the default value during reset. If strap pins are

connected to logic inputs, a stronger external pull-up or pulldown may be required to ensure default value depending on leakage and/or low level input current of the logic load. To set a mode other than the default mode, connect the strap pin to a sufficiently stronger external pull-up or pull-down. [Table 16](#page-19-1) lists and describes each of the DSP's strap pins.

#### <span id="page-19-1"></span>**Table 16. Pin Definitions—I/O Strap Pins**

**I** = input; **A** = asynchronous; **O** = output; **OD** = open-drain output; **T** = three-state; **P** = power supply; **G** = ground; **pd** = internal pull-down 5 kΩ; **pu** = internal pull-up 5 kΩ; **pd\_0** = internal pull-down 5 kΩ on DSP ID = 0; **pu\_0** = internal pull-up 5 kΩ on DSP ID = 0; **pu\_od\_0** = internal pull-up 500 Ω on DSP ID = 0; **pd\_m** = internal pull-down 5 kΩ on DSP bus master; **pu\_m** = internal pull-up 5 kΩ on DSP bus master; **pu\_ad** = internal pull-up 40 kΩ. For more pull-down and pull-up information, see Electrical Characteristics on Page 22.

When default configuration is used, no external resistor is needed on the strap pins. To apply other configurations, a 500 Ω resistor connected to  $V_{DD}$  <sub>IO</sub> is required. If providing external pull-downs, do not strap these pins directly to  $V_{SS}$ ; the strap pins require 500  $\Omega$  resistor straps.

All strap pins are sampled on the rising edge of  $\overline{RST}$  IN (deassertion edge). Each pin latches the strapped pin state (state of the strap pin at the rising edge of  $\overline{\text{RST\_IN}}$ ). Shortly after deassertion of  $\overline{RST}$  IN, these pins are reconfigured to their normal functionality.

These strap pins have an internal pull-down resistor, pull-up resistor, or no-resistor (three-state) on each pin. The resistor type, which is connected to the I/O pad, depends on whether RST\_IN is active (low) or if RST\_IN is deasserted (high). [Table 17](#page-19-2) shows the resistors that are enabled during active reset and during normal operation.

#### <span id="page-19-2"></span>**Table 17. Strap Pin Internal Resistors—Active Reset**   $(\overline{\text{RST\_IN}} = 0)$  vs. Normal Operation  $(\overline{\text{RST\_IN}} = 1)$

## <span id="page-20-1"></span>ADSP-TS202S—SPECIFICATIONS

Note that component specifications are subject to change without notice. For information on link port electrical characteristics, see [Link Port Low Voltage, Differential-Signal](#page-29-0)  [\(LVDS\) Electrical Characteristics, and Timing on Page 30.](#page-29-0)

### <span id="page-20-0"></span>**OPERATING CONDITIONS**

<sup>1</sup>Specifications vary for different grades (for example, SABP-060, SABP-050, SWBP-050). For more information on part grades, see [Ordering Guide on Page 46.](#page-45-0)

<sup>2</sup>V<sub>IH1</sub> specification applies to input and bidirectional pins: SCLKRAT2-0, SCLK, ADDR31-0, DATA63-0, RD, WRL, WRH, ACK, BRST, BR7-0, BOFF, HBR, HBG, MSSD3-0, RAS, CAS, SDCKE, SDWE, TCK, FLAG3–0, DS2–0, ENEDREG.

<sup>3</sup> Values represent dc case. During transitions, the inputs may overshoot or undershoot to the voltage shown in Table 18, based on the transient duty cycle. The dc case is equivalent to 100% duty cycle.

<sup>4</sup> V<sub>IH2</sub> specification applies to input and bidirectional pins: TDI, TMS, TRST, CIMP1-0, ID2-0, LXBCMPI, LxACKI, POR\_IN, RST\_IN, IRQ3-0, CPA, DPA, DMAR3-0.

<sup>5</sup>Applies to input and bidirectional pins.

<sup>6</sup> For details on internal and external power calculation issues, including other operating conditions, see the *EE-170, Estimating Power for the ADSP-TS202S* on the Analog Devices website.

<span id="page-21-1"></span>

 $^{\rm 1}$  The individual values cannot be combined for analysis of a single instance of overshoot or undershoot. The worst case observed value must fall within one of the voltages specified and the total duration of the overshoot or undershoot (exceeding the 100% case) must be less than or equal to the corresponding duty cycle.

 $^2$  Duty cycle refers to the percentage of time the signal exceeds the value for the 100% case. This is equivalent to the measured duration of a single instance of overshoot or undershoot as a percentage of the period of occurrence. The practical worst case for period of occurrence for either overshoot or undershoot is  $2 \times t_{SCLR}$ .

## <span id="page-21-0"></span>**ELECTRICAL CHARACTERISTICS**

Parameter name suffix conventions: no suffix = applies to pins without pull-up or pull-down resistors; **\_PD** = applies to pin types (pd) or (pd\_0); **\_PU** = applies to pin types (pu) or (pu\_0); **\_PU\_AD** = applies to pin types (pu\_ad); **\_OD** = applies to pin types OD; **\_PD\_L** = applies to pin types (pd\_l).

<span id="page-21-2"></span><sup>1</sup> Applies to output and bidirectional pins.

<sup>2</sup> Applies to all signals.

<sup>3</sup> Guaranteed but not tested.

### <span id="page-22-2"></span>**PACKAGE INFORMATION**

The information presented in [Figure 8](#page-22-3) provide details about the package branding for the ADSP-TS202S processors. For a complete listing of product availability, see [Ordering Guide on](#page-45-0)  [Page 46](#page-45-0).

Figure 8. Typical Package Brand

#### <span id="page-22-3"></span>**Table 19. Package Brand Information**

#### <span id="page-22-1"></span>**ESD SENSITIVITY**

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be take to avoid

#### <span id="page-22-0"></span>**ABSOLUTE MAXIMUM RATINGS**

Stresses greater than those listed below may cause permanent damage to the device. These are stress ratings only. Functional operation of the device at these or any other conditions greater than those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

<sup>1</sup> Applies to 10% transient duty cycle. For other duty cycles see [Table 18](#page-21-1).

## <span id="page-23-0"></span>**TIMING SPECIFICATIONS**

With the exception of  $\overline{\mathrm{DMAR3-0}}$ ,  $\overline{\mathrm{IRQ3-0}}$ , TMR0E, and FLAG3–0 (input only) pins, all ac timing for the ADSP-TS202S processor is relative to a reference clock edge. Because input setup/hold, output valid/hold, and output enable/disable times are relative to a clock edge, the timing data for the ADSP-TS202S processor has few calculated (formula-based) values. For information on ac timing, see [General AC Timing](#page-23-1). For information on link port transfer timing, see [Link Port Low](#page-29-0)  [Voltage, Differential-Signal \(LVDS\) Electrical Characteristics,](#page-29-0)  [and Timing on Page 30](#page-29-0).

#### <span id="page-23-1"></span>**General AC Timing**

Timing is measured on signals when they cross the 1.25 V level as described in [Figure 15 on Page 29.](#page-28-0) All delays (in nanoseconds) are measured between the point that the first signal reaches 1.25 V and the point that the second signal reaches 1.25 V.

The general ac timing data appears in [Table 22](#page-23-4) and [Table 29.](#page-27-0) All ac specifications are measured with the load specified in [Figure 36 on Page 38](#page-37-2), and with the output drive strength set to strength 4. In order to calculate the output valid and hold times for different load conditions and/or output drive strengths, refer to [Figure 37 on Page 38](#page-37-3) through [Figure 44 on Page 39](#page-38-0) (Rise and Fall Time vs. Load Capacitance) and [Figure 45 on Page 39](#page-38-1) (Output Valid vs. Load Capacitance and Drive Strength).

The ac asynchronous timing data for the IRQ3–0, DMAR3–0, FLAG3–0, and TMR0E pins appears in Table 21.

#### <span id="page-23-2"></span>**Table 21. AC Asynchronous Signal Specifications**

<span id="page-23-3"></span> $1$ These input pins have Schmitt triggers and therefore do not need to be synchronized to a clock reference.

 $2$  For output specifications on FLAG3–0 pins, see Table 29.

 $3$  This pin is a strap option. During reset, an internal resistor pulls the pin low.

#### <span id="page-23-4"></span>**Table 22. Reference Clocks—Core Clock (CCLK) Cycle Time**

<sup>1</sup> CCLK is the internal processor clock or instruction cycle time. The period of this clock is equal to the system clock period (t<sub>SCLK</sub>) divided by the system clock ratio (SCLKRAT2–0). For information on available part numbers for different internal processor clock rates, see the Ordering Guide on Page 46.

Figure 9. Reference Clocks—Core Clock (CCLK) Cycle Time

#### **Table 23. Reference Clocks—System Clock (SCLK) Cycle Time**

<sup>1</sup> For more information, see Table 3 on Page 12.

<sup>2</sup> [For more information, see Clock Domains on Page 9.](#page-8-3)

 $^3$  The value of (t $_{\rm SCLK}$  / SCLKRAT2-0) must not violate the specification for t $_{\rm CCLK}$ 

 $^4$  System clock transition times apply to minimum SCLK cycle time (t $_{\rm SCLR}$ ) only.

<sup>5</sup> Actual input jitter should be combined with ac specifications for accurate timing analysis.

 $^6$  Jitter specification is maximum peak-to-peak time interval error (TIE) jitter.

Figure 29. Typical Drive Currents at Strength 3

Figure 30. Typical Drive Currents at Strength 4

Figure 31. Typical Drive Currents at Strength 5

Figure 32. Typical Drive Currents at Strength 6

<span id="page-36-2"></span>Figure 33. Typical Drive Currents at Strength 7

### <span id="page-36-0"></span>**TEST CONDITIONS**

The ac signal specifications (timing parameters) appear in [Table 29 on Page 28](#page-27-0). These include output disable time, output enable time, and capacitive loading. The timing specifications for the DSP apply for the voltage reference levels in [Figure 34](#page-36-3).

<span id="page-36-3"></span>Figure 34. Voltage Reference Levels for AC Measurements (Except Output Enable/Disable)

#### <span id="page-36-1"></span>**Output Disable Time**

Output pins are considered to be disabled when they stop driving, go into a high impedance state, and start to decay from their output high or low voltage. The time for the voltage on the bus to decay by  $\Delta V$  is dependent on the capacitive load,  $C<sub>L</sub>$  and the load current, I<sub>L</sub>. This decay time can be approximated by the following equation:

$$
t_{DECAY} = (C_L \Delta V) / I_L
$$

The output disable time t<sub>DIS</sub> is the difference between  ${\rm t_{MEASURED\_DIS}}$  and  ${\rm t_{DECAY}}$  as shown in Figure 35. The time  $\overline{t_{\text{MEASURED}}_{\text{DIS}}}$  is the interval from when the reference signal switches to when the output voltage decays ∆V from the measured output high or output low voltage.  $t_{\text{DECAY}}$  is calculated with test loads C<sub>L</sub> and I<sub>L</sub>, and with  $\Delta V$  equal to 0.4 V.

<span id="page-36-4"></span>Figure 35. Output Enable/Disable

#### <span id="page-37-0"></span>**Output Enable Time**

Output pins are considered to be enabled when they have made a transition from a high impedance state to when they start driving. The time for the voltage on the bus to ramp by ∆V is dependent on the capacitive load,  $C_L$ , and the drive current,  $I_D$ . This ramp time can be approximated by the following equation:

$$
t_{RAMP} = (C_L \Delta V) / I_D
$$

The output enable time  $t_{ENA}$  is the difference between  $t_{MEASURED-ENA}$  and  $t_{RAMP}$  as shown in Figure 35. The time  $t_{MEASURED-ENA}$  is the interval from when the reference signal switches to when the output voltage ramps ∆V from the measured three-stated output level.  $t_{\mathrm{RAMP}}$  is calculated with test load  $\rm C_L$  drive current I<sub>D</sub>, and with  $\Delta \rm V$  equal to 0.4 V.

#### <span id="page-37-1"></span>**Capacitive Loading**

Output valid and hold are based on standard capacitive loads: 30 pF on all pins (see Figure 36). The delay and hold specifications given should be derated by a drive strength related factor for loads other than the nominal value of 30 pF. Figure 37 through [Figure 44](#page-38-0) show how output rise time varies with capacitance. [Figure 45](#page-38-1) graphically shows how output valid varies with load capacitance. (Note that this graph or derating does not apply to output disable delays; see Output Disable Time on [Page 37](#page-36-1).) The graphs of Figure 37 through Figure 45 may not be linear outside the ranges shown.

<span id="page-37-2"></span>Figure 36. Equivalent Device Loading for AC Measurements (Includes All Fixtures)

<span id="page-38-0"></span>Figure 44. Typical Output Rise and Fall Time (10% to 90%,  $V_{DD\_IO} = 2.5 V$ ) vs. Load Capacitance at Strength 7

<span id="page-38-1"></span>Figure 45. Typical Output Valid ( $V_{DD\_IO}$  = 2.5 V) vs. Load Capacitance at Max Case Temperature and Strength 0 to  $7^1$ 

 $1$ <sup>1</sup> The line equations for the output valid vs. load capacitance are:

Strength  $0: y = 0.0956x + 3.5662$ Strength  $1: y = 0.0523x + 3.2144$ Strength 2: y = 0.0433x + 3.1319 Strength 3: y = 0.0391x + 2.9675 Strength 4:  $y = 0.0393x + 2.7653$ Strength 5:  $y = 0.0373x + 2.6515$ Strength 6: y = 0.0379x + 2.1206 Strength 7: y = 0.0399x + 1.9080

## <span id="page-39-0"></span>**ENVIRONMENTAL CONDITIONS**

The ADSP-TS202S processor is rated for performance under T<sub>CASE</sub> environmental conditions specified in the [Operating Con](#page-20-0)[ditions on Page 21](#page-20-0).

### <span id="page-39-1"></span>**Thermal Characteristics**

The ADSP-TS202S processor is packaged in a 25 mm  $\times$  25 mm, thermally enhanced ball grid array (BGA\_ED). The ADSP-TS202S processor is specified for a case temperature ( $T_{\mathrm{CASE}}$ ). To ensure that the  $T_{\mathrm{CASE}}$  data sheet specification is not exceeded, a heat sink and/or an air flow source may be required.

[Table 34](#page-39-2) shows the thermal characteristics of the 25 mm × 25 mm BGA\_ED package. All parameters are based on a JESD51-9 four-layer 2s2p board. All data are based on 3 W power dissipation.

#### <span id="page-39-2"></span>**Table 34. Thermal Characteristics for 25 mm × 25 mm Package**

 $1\theta$ <sub>JA</sub> measured per JEDEC standard JESD51-6.

 $^{2}$   $\theta$ <sub>IA</sub> = 12.9°C/W for 0 m/s is for vertically mounted boards. For horizontally mounted boards, use 17.0°C/W for 0 m/s.

 $3\theta_{\text{IB}}$  measured per JEDEC standard JESD51-9.

 ${}^{4} \theta_{\text{JC}}$  measured by cold plate test method (no approved JEDEC standard).

## <span id="page-40-0"></span>576-BALL BGA\_ED PIN CONFIGURATIONS

[Figure 46](#page-40-1) shows a summary of pin configurations for the 576-ball BGA\_ED package, and [Table 35](#page-41-0) lists the signal-to-ball assignments.

**TOP VIEW**

Figure 46. 576-Ball BGA\_ED Pin Configurations<sup>1</sup> (Top View, Summary)
