3A, 21V 500kHz Synchronous Step-Down Converter

General Description

The RT7263B is a synchronous step-down regulator with an internal power MOSFET. It achieves 3A of continuous output current over a wide input supply range with excellent load and line regulation. Current mode operation provides fast transient response and eases loop stabilization.

Fault condition protection includes cycle-by-cycle current limiting and thermal shutdown. An adjustable soft-start reduces the stress on the input source at startup.

The RT7263B requires a minimal number of readily available external components, providing a compact solution.

Ordering Information

Package Type QW : WDFN-14L 4x3 (W-Type) RT7263B_D

> Lead Plating System Z : ECO (Ecological Element with Halogen Free and Pb free)

Note :

Richtek products are :

- ` RoHS compliant and compatible with the current require ments of IPC/JEDEC J-STD-020.
- ` Suitable for use in SnPb or Pb-free soldering processes.

Features

- Wide Input Range: 4.5V to 21V
- **Adjustable Output from 0.603V to 15V**
- **3A Output Current**
- ^z **120m**Ω**/40m**Ω **Internal Power MOSFET Switch**
- **Internal Compensation Minimizes External Parts**
- \bullet **500kHz Fixed Switching Frequency**
- \bullet **Synchronized External Clock from 300kHz to 2MHz**
- **Adjustable Soft-Start**
- **Cycle-by-Cycle Over Current Limit**
- **Thermal Shutdown Protection**
- **Small 14-Lead WDFN Package**
- **RoHS Compliant and Halogen Free**

Applications

- Distributive Power Systems
- Battery Charger
- DSL Modems
- Pre-Regulator for Linear Regulators

Marking Information

Simplified Application Circuit

Pin Configurations

Function Pin Description

Function Block Diagram

Operation

The RT7263B is a constant frequency, current mode synchronous step-down converter. In normal operation, the high side N-MOSFET is turned on when the S-R latch is set by the oscillator and is turned off when the current comparator resets the S-R latch. While the high side N-MOSFET is turned off, the low side N-MOSFET is turned on to conduct the inductor current until next cycle begins.

Error Amplifier

The error amplifier adjusts its output voltage by comparing the feedback signal (V_{FB}) with the internal reference. When the load current increases, it causes a drop in the feedback voltage relative to the reference, the error amplifier's output voltage then rises to allow higher inductor current to match the load current.

Oscillator

The internal oscillator runs at fixed frequency 500kHz. In short circuit condition, the frequency is reduced to 150kHz for low power consumption.

Internal Regulator

The regulator provides low voltage power to supply the internal control circuits and the bootstrap power for high side gate driver.

Enable

The converter is turned on when the EN pin is higher than 2V. When the EN pin is lower than 0.4V, the converter will enter shutdown mode and reduce the supply current to be less than 1µA.

Soft-Start (SS)

An internal current source charges an internal capacitor to build a soft-start ramp voltage. The FB voltage will track the internal ramp voltage during soft-start interval. The typical soft-start time is 4ms.

UV Comparator

If the feedback voltage (V_{FB}) is lower than 0.4V, the UV Comparator will go high to turn off the high side MOSFET. The output under voltage protection is designed to operate in Hiccup mode. When the UV condition is removed, the converter will resume switching.

Thermal Shutdown

The over temperature protection function will shut down the switching operation when the junction temperature exceeds 150°C. Once the junction temperature cools down by approximately 30°C, the converter will automatically resume switching.

- **Note 1.** Stresses beyond those listed " Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.
- **Note 2.** $θ_{JA}$ is measured at T_A = 25°C on a high effective thermal conductivity four-layer test board per JEDEC 51-7. $θ_{JC}$ is measured at the exposed pad of the package.
- **Note 3.** Devices are ESD sensitive. Handling precaution is recommended.
- **Note 4.** The device is not guaranteed to function outside its operating conditions.

Application Information

The IC is a synchronous high voltage step-down converter that can support the input voltage range from 4.5V to 21V and the output current can be up to 3A.

Output Voltage Setting

The output voltage is set by an external resistive divider according to the following equation :

 $V_{\text{OUT}} = V_{\text{FB}} \left(1 + \frac{R1}{R2} \right)$

where V_{FB} is the feedback reference voltage 0.603V (typ.).

The resistive divider allows the FB pin to sense a fraction of the output voltage as shown in Figure 1.

Figure 1. Output Voltage Setting

External Bootstrap Diode

Connect a 100nF low ESR ceramic capacitor between the BOOT pin and SW pin as shown in Figure 2. This capacitor provides the gate driver voltage for the high side MOSFET. It is recommended to add an external bootstrap diode between an external 5V and BOOT pin for efficiency improvement when input voltage is lower than 5.5V or duty ratio is higher than 65% .The bootstrap diode can be a low cost one such as IN4148 or BAT54. The external 5V can be a 5V fixed input from system or a 5V output of the IC. Note that the external boot voltage must be lower than 5.5V.

Figure 2. External Bootstrap Diode

Soft-Start

The IC contains an external soft-start clamp that gradually raises the output voltage. The soft-start timing is programmed by the external capacitor between SS pin and GND. The chip provides an internal 10µA charge current for the external capacitor. If 47nF capacitor is used to set the soft-start, the period will be 4.7ms (typ.).

Under Voltage Lockout Threshold

The IC includes an input Under Voltage Lockout Protection (UVLO). If the input voltage exceeds the UVLO rising threshold voltage (4.2V), the converter resets and prepares the PWM for operation. If the input voltage falls below the UVLO falling threshold voltage (3.8V) during normal operation, the device stops switching. The UVLO rising and falling threshold voltage includes a hysteresis to prevent noise caused reset.

Chip Enable Operation

The EN pin is the chip enable input. Pulling the EN pin low (<0.4V) will shutdown the device. During shutdown mode, the RT7263B quiescent current drops to lower than 1µA. Driving the EN pin high (2V < EN < 5.5V) will turn on the device again. For external timing control, the EN pin can also be externally pulled high by adding a R_{EN} resistor and C_{EN} capacitor from the VIN pin (see Figure 3).

Figure 3. Enable Timing Control

An external MOSFET can be added to implement digital control on the EN pin, as shown in Figure 4. In this case, a 100kΩ pull-up resistor, R_{EN}, is connected between V_{IN} pin and the EN pin. MOSFET Q1 will be under logic control to pull down the EN pin.

RT7263B

Figure 4. Digital Enable Control Circuit

The chip starts to operate when V_{IN} rises to 4.2V (UVLO threshold). During the V_{IN} rising period, if an 8V output voltage is set, V_{IN} is lower than the V_{OUT} target value and it may cause the chip to shut down. To prevent this situation, a resistive voltage divider can be placed between the input voltage and ground and connected to the EN pin to adjust enable threshold, as shown in Figure 5. For example, the setting V_{OUT} is 8V and V_{IN} is from 0V to 12V, when V_{IN} is higher than 10V, the chip is triggered to enable the converter. Assume $R_{EN1} = 50k\Omega$. Then,

$$
R_{EN2} = \frac{(R_{EN1} \times V_{IH(MIN)})}{(V_{IN_S} - V_{IH(MIN)})}
$$

where $V_{\text{IH}(M|N)}$ is the minimum threshold of enable rising (2V) and V_{IN-S} is the target turn on input voltage (10V in this example). According to the equation, the suggested resistor R $_{EN2}$ is 12.5kΩ.

Figure 5. Resistor Divider for Lockout Threshold Setting

Operating Frequency and Synchronization

The internal oscillator runs at 500kHz (typ.) when the EN/ SYNC pin is at logic-high level (>2V). If the EN pin is pulled to low-level for 10µs above, the IC will shut down. The RT7263B can be synchronized with an external clock ranging from 300kHz to 2MHz applied to the EN/SYNC pin. The external clock duty cycle must be from 30% to 90%.

Figure 6. Startup Sequence Using External Sync Clock

Figure 6 shows the synchronization operation in startup period. When the EN/SYNC is triggered by an external clock, the RT7263B enters soft-start phase and the output voltage starts to rise. During the soft-start phase region, the oscillation frequency will be proportional to the feedback voltage until it is higher than 0.7V. With higher V_{FB} , the switching frequency is relatively higher. After startup period about 2ms, the IC operates with the same frequency as the external clock.

Output Under Voltage Protection (Hiccup Mode)

For the IC, Hiccup Mode of Under Voltage Protection (UVP) is provided. When the FB voltage drops below half of the feedback reference voltage, V_{FB} , the UVP function will be triggered and the IC will shut down for a period of time and then recover automatically. The Hiccup Mode of UVP can reduce input current in short-circuit conditions.

Inductor Selection

For a given input and output voltage, the inductor value and operating frequency determine the ripple current. The ripple current ∆I_L increases with higher V_{IN} and decreases with higher inductance.

$$
\Delta I_L = \left[\frac{V_{OUT}}{f \times L} \right] \times \left[1 - \frac{V_{OUT}}{V_{IN}} \right]
$$

Having a lower ripple current reduces not only the ESR losses in the output capacitors but also the output voltage ripple. Highest efficiency operation is achieved by reducing ripple current at low frequency, but it requires a large inductor to attain this goal.

For the ripple current selection, the value of $\Delta I_L = 0.24(I_{MAX})$ will be a reasonable starting point. The largest ripple current occurs at the highest V_{IN} . To guarantee that the ripple current stays below a specified maximum, the inductor value should be chosen according to the following equation :

OUT OUT $L = \left[\frac{V_{\text{OUT}}}{f \times \Delta I_{\text{L(MAX)}}} \right] \times \left[1 - \frac{V_{\text{OUT}}}{V_{\text{IN(MAX)}}} \right]$

The inductor's current rating (caused a 40°C temperature rising from 25°C ambient) should be greater than the maximum load current and its saturation current should be greater than the short circuit peak current limit. Please see Table 2 for the inductor selection reference and it is highly recommended to keep inductor value as close as possible to the recommended inductor values for each V_{OUT} as shown in Table 1.

Table 2. Suggested Inductors for Typical Application Circuit

Component Supplier	Series	Dimensions (mm)
TDK	VLF10045	$10 \times 9.7 \times 4.5$
TDK	SLF12565	$12.5 \times 12.5 \times 6.5$
TAIYO YUDEN	NR8040	$8 \times 8 \times 4$

Input and Output Capacitors Selection

The input capacitance, C_{IN} , is needed to filter the trapezoidal current at the source of the high side MOSFET. To prevent large ripple current, a low ESR input capacitor sized for the maximum RMS current should be used. The RMS current is given by :

$$
I_{RMS} = I_{OUT(MAX)} \frac{V_{OUT}}{V_{IN}} \sqrt{\frac{V_{IN}}{V_{OUT}} - 1}
$$

This formula has a maximum at $V_{IN} = 2V_{OUT}$, where $I_{RMS} =$ I_{OUT} / 2. This simple worst case condition is commonly used for design because even significant deviations do not offer much relief.

Choose a capacitor rated at a higher temperature than required. Several capacitors may also be paralleled to meet size or height requirements in the design.

For the input capacitor, one 22µF low ESR ceramic capacitors are recommended. For the recommended capacitor, please refer to table 3 for more detail.

The selection of C_{OUT} is determined by the required ESR to minimize voltage ripple.

Moreover, the amount of bulk capacitance is also a key for C_{OUT} selection to ensure that the control loop is stable. Loop stability can be checked by viewing the load transient response.

The output ripple, ΔV_{OUT} , is determined by :

$$
\Delta V_{OUT} \leq \Delta I_L \Bigg[ESR + \frac{1}{8fC_{OUT}} \Bigg]
$$

Higher values, lower cost ceramic capacitors are now becoming available in smaller case sizes. Their high ripple current, high voltage rating and low ESR make them ideal for switching regulator applications. However, care must be taken when these capacitors are used at input and output. When a ceramic capacitor is used at the input and the power is supplied by a wall adapter through long wires, a load step at the output can induce ringing at the input, V_{IN} . At best, this ringing can couple to the output and be mistaken as loop instability. At worst, a sudden inrush of current through the long wires can potentially cause a voltage spike at V_{IN} large enough to damage the part.

Thermal Shutdown

Thermal shutdown in implemented to prevent the chip from operating at excessively high temperatures. When the junction temperature is higher than 150°C, the chip is shut down the switching operation. The chip is automatically re-enabled when the junction temperature cools down by approximately 30°C.

Thermal Considerations

For continuous operation, do not exceed absolute maximum junction temperature. The maximum power dissipation depends on the thermal resistance of the IC package, PCB layout, rate of surrounding airflow, and difference between junction and ambient temperature. The maximum power dissipation can be calculated by the following formula :

 $P_{D(MAX)} = (T_{J(MAX)} - T_A)/\theta_{JA}$

where $T_{J(MAX)}$ is the maximum junction temperature, T_A is the ambient temperature, and θ_{JA} is the junction to ambient thermal resistance.

For recommended operating condition specifications, the maximum junction temperature is 125°C. The junction to ambient thermal resistance, θ_{JA} , is layout dependent. For WDFN-14L 4x3 package, the thermal resistance, θ_{JA} , is 60°C/W on a standard JEDEC 51-7 four-layer thermal test board. The maximum power dissipation at $T_A = 25^{\circ}$ C can be calculated by the following formula :

 $P_{D(MAX)} = (125 °C - 25 °C) / (60 °C/W) = 1.667 W$ for WDFN-14L 4x3 package

The maximum power dissipation depends on the operating ambient temperature for fixed $T_{J(MAX)}$ and thermal resistance, θ_{JA} . The derating curve in Figure 7 allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Layout Considerations

Follow the PCB layout guidelines for optimal performance of the IC.

- \triangleright Keep the traces of the main current paths as short and wide as possible.
- \triangleright Put the input capacitor as close as possible to the device pins (VIN and GND).
- \triangleright SW node is with high frequency voltage swing and should be kept at small area. Keep analog components away from the SW node to prevent stray capacitive noise pickup.
- ▶ Connect feedback network behind the output capacitors. Keep the loop area small. Place the feedback components near the IC.
- \triangleright Connect all analog grounds to a common node and then connect the command node to the power ground behind the output capacitors.
- ▶ An example of PCB layout guide is shown in Figure 8 for reference.

RT7263B

SW should be connected to inductor by wide and short trace and keep sensitive components away from this trace.
