

FEATURES

- Excellent Temperature Stability (20ppm/°C)
- Linear Frequency Sweep
- Wide Sweep Range (1000:1 Minimum)
- Wide Supply Voltage Range ($\pm 4V$ to $\pm 13V$)
- Low Supply Sensitivity (0.1% /V)
- Wide Frequency Range (0.01Hz to 1MHz)
- Simultaneous Triangle and Squarewave Outputs

APPLICATIONS

- Voltage and Current-to-Frequency Conversion
- Stable Phase-Locked Loop
- Waveform Generation
Triangle, Sawtooth, Pulse, Squarewave
- FM and Sweep Generation

GENERAL DESCRIPTION

The XR-2209 is a monolithic voltage-controlled oscillator (VCO) integrated circuit featuring excellent frequency stability and a wide tuning range. The circuit provides simultaneous triangle and squarewave outputs over a frequency range of 0.01Hz to 1MHz. It is ideally suited for FM, FSK, and sweep or tone generation, as well as for

phase-locked loop applications.

The oscillator of the XR-2209 has a typical drift specification of 20ppm/°C. The oscillator frequency can be linearly swept over a 1000:1 range with an external control voltage.

ORDERING INFORMATION

Part No.	Package	Operating Temperature Range
XR-2209CN	8 Lead 300 Mil CDIP	0° to +70°C
XR-2209M	8 Lead 300 Mil CDIP	-55°C to +125°C
XR-2209CP	8 Lead 300 Mil PDIP	0°C to +70°C

PRECAUTIONS

The following precautions should be observed when operating the XR-2209 family of integrated circuits:

1. Pulling excessive current from the timing terminals will adversely affect the temperature stability of the circuit. To minimize this disturbance, it is recommended that the total current drawn from pin 4 be limited to $\leq 6\text{mA}$. In addition, permanent damage to the device may occur if the total timing current exceeds 10mA.
2. Terminals 2, 3, and 4 have very low internal impedance and should, therefore, be protected from accidental shorting to ground or the supply voltage.

SYSTEM DESCRIPTION

The XR-2209 functional blocks are shown in the block diagram given in *Figure 1*. They are a voltage controlled oscillator (VCO), and two buffer amplifiers for triangle and squarewave outputs. *Figure 2* is a simplified XR-2209 schematic diagram that shows the circuit in greater detail.

The VCO is a modified emitter-coupled current controlled multivibrator. Its oscillation is inversely proportional to the value of the timing capacitor connected to pins 2 and 3, and directly proportional to the total timing current I_T . This current is determined by the resistor that is connected from the timing terminals (pin 4) to ground.

The triangle output buffer has a low impedance output (10Ω typ.) while the squarewave is an open-collector type. An external bias input allows the XR-2209 to be used in either single or split supply applications.

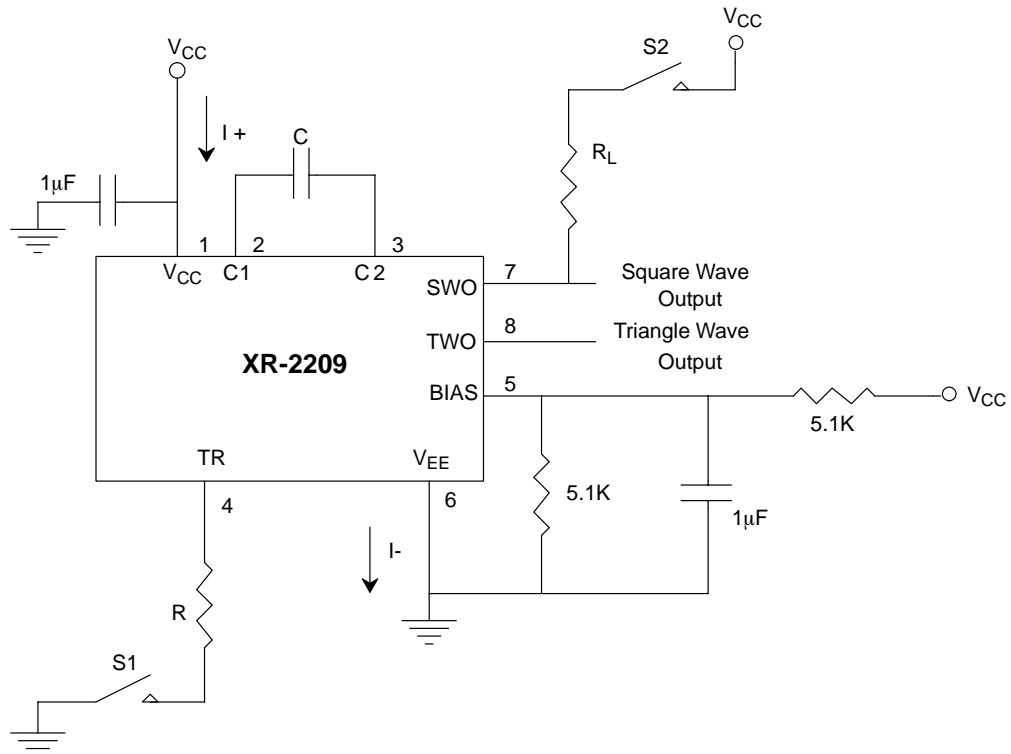

Figure 3. Test Circuit for Single Supply Operation

Figure 4. Test Circuit for Split Supply Operation

OPERATING CONSIDERATIONS

Supply Voltage (Pins 1 and 6)

The XR-2209 is designed to operate over a power supply range of $\pm 4V$ to $\pm 13V$ for split supplies, or 8V to 26V for single supplies. *Figure 5* shows the permissible supply voltage for operation with unequal split supply voltages. *Figure 6* and *Figure 7* show supply current versus supply voltage. Performance is optimum for $\pm 6V$ split supply, or 12V single supply operation. At higher supply voltages, the frequency sweep range is reduced.

Ground (Pin 6)

For split supply operation, this pin serves as circuit ground. For single supply operation, pin 6 should be ac grounded through a $1\mu F$ bypass capacitor. During split supply operation, a ground current of $2 I_T$ flows out of this terminal, where I_T is the total timing current.

Bias for Single Supply (Pin 5)

For single supply operation, pin 5 should be externally biased to a potential between $V_{CC}/3$ and $V_{CC}/2V$ (see *Figure 3*.) The bias current at pin 5 is nominally 5% of the total oscillation timing current, I_T .

Bypass Capacitors

The recommended value for bypass capacitors is $1\mu F$ although larger values are required for very low frequency operation.

Timing Resistor (Pin 4)

The timing resistor determines the total timing current, I_T , available to charge the timing capacitor. Values for the timing resistor can range from $2k\Omega$ to $2M\Omega$; however, for optimum temperature and power supply stability, recommended values are $4k\Omega$ to $200k\Omega$ (see *Figure 8*, *Figure 9*, *Figure 10* and *Figure 11*.) To avoid parasitic pick up, timing resistor leads should be kept as short as possible.

Timing Capacitor (Pins 2 and 3)

The oscillator frequency is inversely proportional to the timing capacitor, C. The minimum capacitance value is limited by stray capacitances and the maximum value by

physical size and leakage current considerations. Recommended values range from 100pF to 100μF. The capacitor should be non-polarized.

Figure 8. Recommended Timing Resistor Value vs. Power Supply Voltage

Figure 9. Frequency Accuracy vs. Timing Resistance

Figure 10. Frequency Drift vs. Supply Voltage

Figure 11. Normalized Frequency Drift with Temperature

Squarewave Output (Pin 7)

The squarewave output at pin 7 is an “open-collector” stage capable of sinking up to 20mA of load current. R_L serves as a pull-up load resistor for this output. Recommended values for R_L range from 1k Ω to 100k Ω .

Triangle Output (Pin 8)

The output at pin 8 is a triangle wave with a peak swing of approximately one-half of the total supply voltage. Pin 8 has a 10 Ω output impedance and is internally protected against short circuits.

MODES OF OPERATION

Split Supply Operation

Figure 12 is the recommended configuration for split supply operation. Diode D_1 in the figure assures that the triangle output swing at pin 8 is symmetrical about ground. The circuit operates with supply voltages ranging from $\pm 4V$ to $\pm 13V$. Minimum drift occurs with $\pm 6V$ supplies. For operation with unequal supply voltages, see Figure 5.

With the generalized circuit of Figure 12, the frequency of

operation is determined by the timing capacitor, C , and the timing resistor.

The squarewave output is obtained at pin 7 and has a peak-to-peak voltage swing equal to the supply voltages. This output is an "open-collector" type and requires an external pull-up load resistor (nominally $5k\Omega$) to the positive supply. The triangle waveform obtained at pin 8 is centered about ground and has a peak amplitude of $V_{CC}/2$.

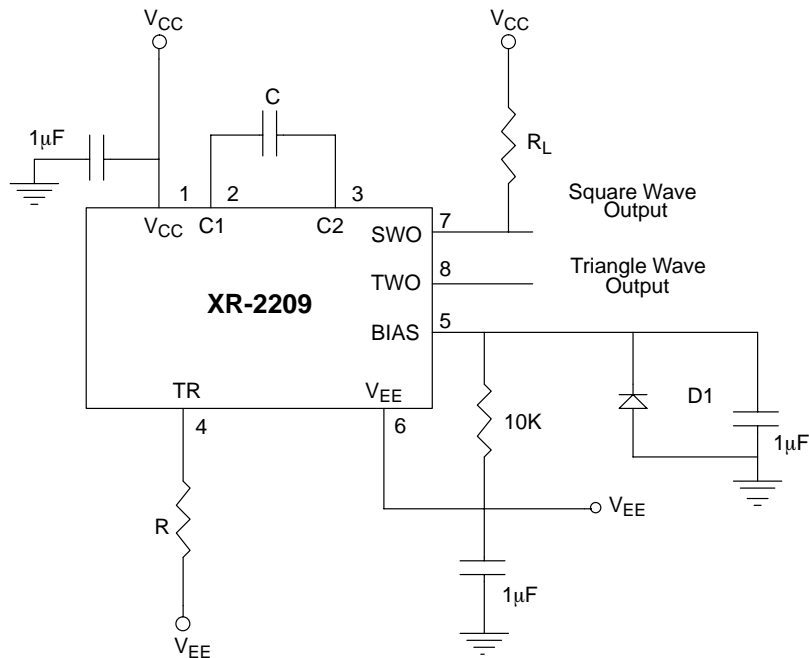

Figure 12. Split-Supply Operation, Recommended Configuration

Figure 13 is a simplified configuration for operation with split supplies in excess of $\pm 7V$. This circuit eliminates the diode D1 used in Figure 12 by grounding pin 5 directly;

however, the triangle wave output now has a +0.6V DC offset with respect to ground.

Figure 13. Split-Supply Operation, Simplified Configuration

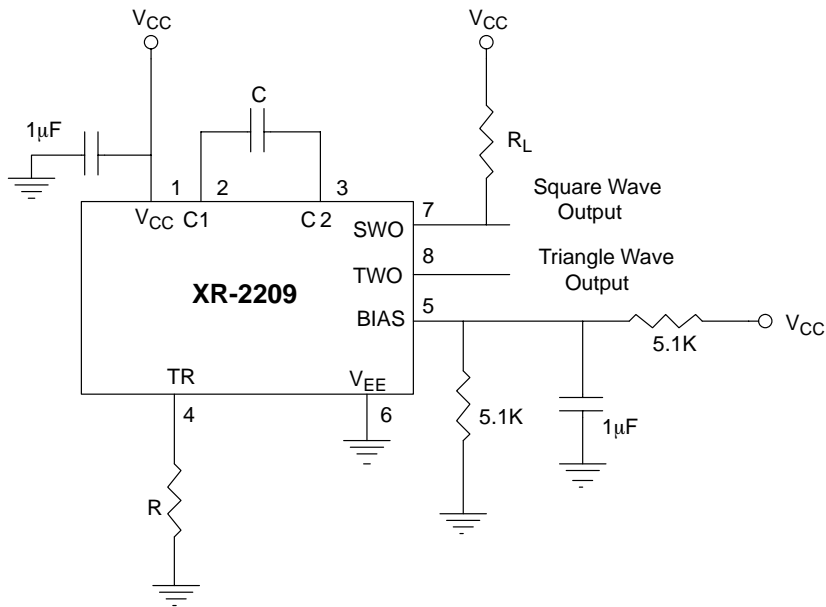

Figure 14. Single Supply Operation

Single Supply Operation

The circuit should be interconnected as shown in *Figure 14* for single supply operation. Pin 6 should be grounded, and pin 5 biased from V_{CC} through a resistive divider to a value of bias voltage between $V_{CC}/3$ and $V_{CC}/2$.

The frequency of operation is determined by the timing capacitor C and the timing resistor R , and is equal to $1/RC$. The squarewave output is obtained at pin 7 and has a peak-to-peak voltage swing equal to the supply voltage. This output is an “open-collector” type and requires an external pull-up load resistor (nominally $5k\Omega$) to $V+$. The triangle waveform obtained at pin 8 is centered about a voltage level V_O where:

$$V_O = V_B + 0.6V$$

where V_B is the bias voltage at pin 5. The peak-to-peak output swing of triangle wave is approximately equal to $V_{CC}/2$.

Frequency Control (Sweep and FM) - Split Supply

The circuit given in *Figure 15* shows a frequency sweep method for split supply operation.

The frequency of operation is controlled by varying the total timing current, I_T , drawn from the activated timing pin 4. The timing current can be modulated by applying a control voltage, V_C , to the timing pin through a series resistor R . As the control voltage becomes more negative, both the total timing current, I_T , and the oscillation frequency increase.

The frequency of operation, is now proportional to the control voltage, V_C , and determined as:

$$f = \frac{1}{RC} \left[1 + \frac{V_C R}{R_C V_{EE}} \right] \text{ Hz}$$

If $R = 2M\Omega$, $R_C = 2k\Omega$, $C = 5000pF$, then a 1000:1 frequency sweep would result for a negative sweep voltage $V_C \approx V_{EE}$.

The voltage to frequency conversion gain, K , is controlled by the series resistance R_C and can be expressed as:

$$K = \frac{\Delta f}{\Delta V_C} = -\frac{1}{R_C C V_{EE}} \text{ Hz/V}$$

The circuit of *Figure 15* can operate both with positive and negative values of control voltage. However, for positive values of V_C with small (R_C/R) ratio, the direction of the timing current I_T is reversed and the oscillations will stop.

Frequency Control (Sweep and FM) - Single Supply

The circuit given in *Figure 16* shows the frequency sweep method for single supply operation. Here, the oscillation

frequency is given as:

$$f = \frac{1}{RC} \left[1 + \frac{R}{R_C} \left(1 - \frac{V_C}{V_T} \right) \right]$$

where $V_T = V_{pin4} \sim V_{bias} + 0.7V$.

This equation is valid from $V_C = 0V$ where R_C is in parallel with R and I_T is maximum to:

$$V_C = V_T \left(1 + \frac{R_C}{R} \right)$$

where $I_T = 0$ and oscillation ceases.

Caution: Total timing current I_T must be less than 6mA over the frequency control range.
