

HA456

120MHz, Low Power, 8x8 Video Crosspoint Switch

FN4153

Rev 7.00

September 26, 2008

The HA456 is the first 8x8 video crosspoint switch suitable for high performance video systems. Its high level of integration significantly reduces component count, board space, and cost. The crosspoint switch contains a digitally controlled matrix of 64 fully buffered switches that connect 8 video input signals to any, or all, matrix outputs. Each matrix output connects to an internal, high-speed (200V/μs), unity gain buffer capable of driving 400Ω and 5pF to ±2V.

For applications requiring gain or increased drive capability, the HA456 outputs can be connected directly to two HFA1412 quad, gain of two video buffers, which are capable of driving 75Ω loads.

This crosspoint's true high impedance three-state output capability, makes it feasible to parallel multiple HA456s and form larger switch matrices.

Ordering Information

PART NUMBER	PART MARKING	TEMP. RANGE (°C)	PACKAGE	PKG. DWG. #
HA456CM	HA456CM	0 to +70	44 Ld PLCC	N44.65
HA456CMZ (Note)	HA456CMZ	0 to +70	44 Ld PLCC (Pb-free)	N44.65

NOTE: These Intersil Pb-free plastic packaged products employ special Pb-free material sets, molding compounds/die attach materials, and 100% matte tin plate plus anneal (e3 termination finish, which is RoHS compliant and compatible with both SnPb and Pb-free soldering operations). Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Features

- Fully Buffered Inputs and Outputs (A_V = +1)
- Routes Any Input Channel to Any Output Channel
- Switches Standard and High Resolution Video Signals
- Serial or Parallel Digital Interface
- Expandable for Larger Switch Matrices
- Wide Bandwidth 120MHz
- High Slew Rate 200V/μs
- Differential Gain and Phase 0.05%, 0.05°
- Low Crosstalk at 10MHz -55dB
- Pb-Free Available (RoHS Compliant)

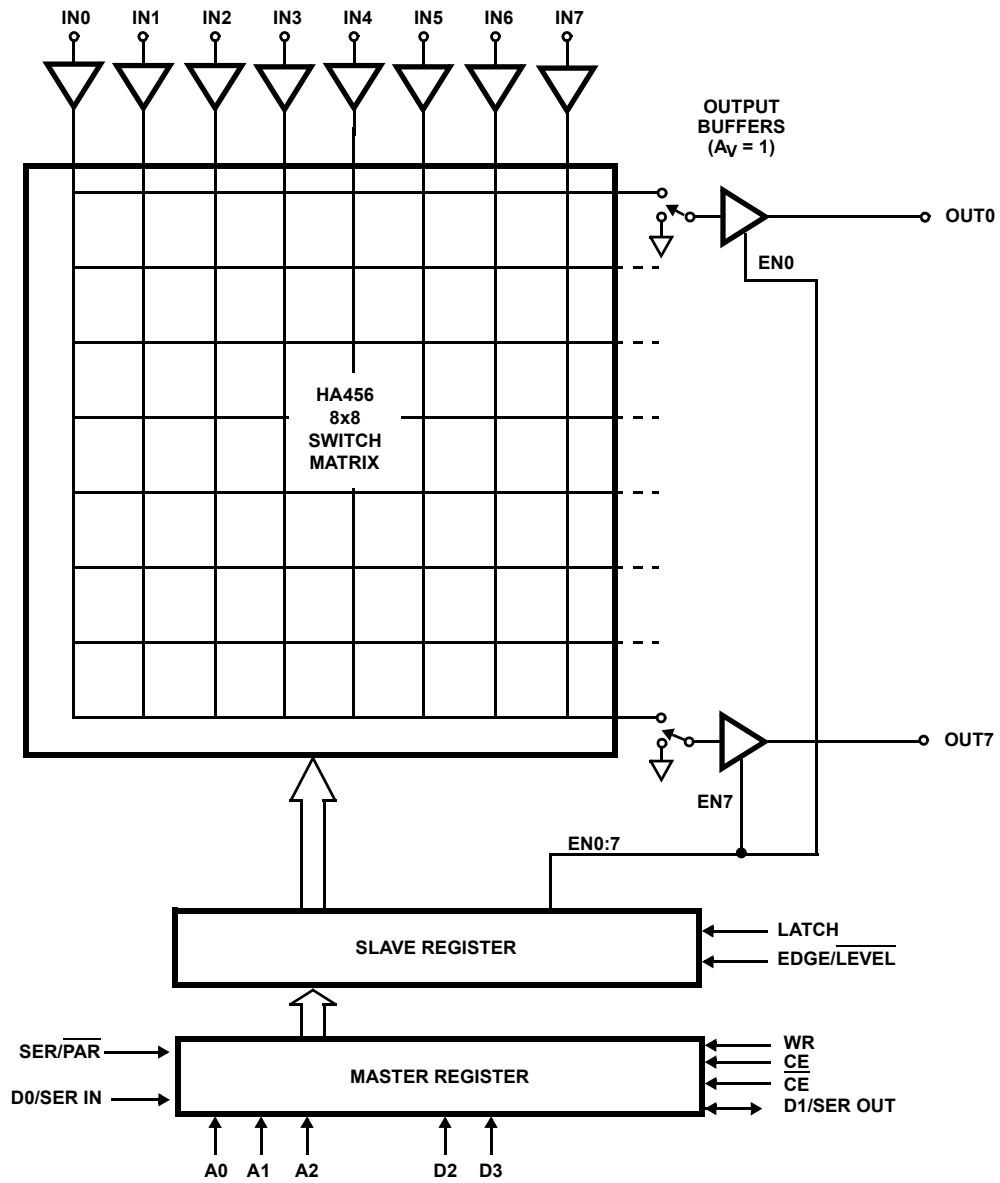

Applications

- Professional Video Switching and Routing
- Security and Video Editing Systems

Pinout

HA456 Functional Block Diagram

Pin Descriptions

NAME	FUNCTION
NC	No connect. Not internally connected.
D1/SER OUT	Parallel Data Bit input D1 for Parallel Programming Mode. Serial Data Output (MSB of shift register) for cascading multiple HA456s in serial programming mode. Simply connect Serial Data Out of one HA456 to Serial Data In of another HA456 to daisy chain multiple devices.
D0/SER IN	Parallel Data Bit Input D0 for Parallel Programming Mode. Serial Data Input (input to shift register) for serial programming mode.
A2, A1, A0	Output Channel Address Bits. These inputs select the output being programmed in parallel programming mode.
IN0-IN7	Analog Video Input Lines.
DGND	Digital Ground. Connect both DGND pins to AGND.
EDGE/ $\overline{\text{LEVEL}}$	A user strapped input that defines whether synchronous channel switching is edge or level controlled. With this pin is strapped high, the slave register loads from the master register (thus changing the switch matrix state) on the rising edge of the LATCH signal. If it is strapped low (level mode), the slave register is transparent while LATCH is low, passing data directly from the master register to the switch state decoders. Strapping EDGE/ $\overline{\text{LEVEL}}$ and LATCH low causes the channel switch to execute on the WR rising edge (not recommended for serial mode operation).
V+	Positive Supply Voltage. Connect all V+ pins together and decouple each pin to AGND (see Figure 2).
SER/ $\overline{\text{PAR}}$	A user strapped input that defines whether the serial (SER/ $\overline{\text{PAR}}$ = 1) or parallel (SER/ $\overline{\text{PAR}}$ = 0) digital programming interface is being utilized.
V-	Negative Supply Voltage. Connect both V- pins together and decouple each pin to AGND (see Figure 2).
WR	WRITE Input. In serial mode, data shifts into the shift register (Master Register) LSB from SER IN on the WR rising edge. In parallel mode, the Master Register loads with D3:0 (if D3:0 = 0000 through 1000), or the appropriate action is taken (if D3:0 = 1011 through 1111), on the WR rising edge (see Table 1).
LATCH	Synchronous Channel Switch Control Input. If EDGE/ $\overline{\text{LEVEL}}$ = 1, data is loaded from the Master Register to the Slave Register on the rising edge of LATCH. If EDGE/ $\overline{\text{LEVEL}}$ = 0, data is loaded from the Master to the Slave Register while LATCH = 0. In parallel mode, commands 1011 through 1110 execute asynchronously, on the WR rising edge, regardless of the state of LATCH or EDGE/ $\overline{\text{LEVEL}}$. Parallel mode command 1111 executes a software "Latch" (see Table 1).
$\overline{\text{CE}}$	Chip Enable. When $\overline{\text{CE}}$ = 0 and CE = 1, the WR line is enabled.
CE	Chip Enable. When $\overline{\text{CE}}$ = 0 and CE = 1, the WR line is enabled.
OUT7-OUT0	Analog Video Outputs.
AGND	Analog Ground.
D3	Parallel Data Bit Input D3 when SER/ $\overline{\text{PAR}}$ = 0. D3 is unused with serial programming.
D2	Parallel Data Bit Input D2 when SER/ $\overline{\text{PAR}}$ = 0. D2 is unused with serial programming.

Absolute Maximum Ratings

Supply Voltage (V+ to V-)	12V
Positive Supply Voltage (V+) Referred to AGND	6V
Negative Supply Voltage (V-) Referred to AGND	-6V
DGND Voltage	AGND \pm 1V
Analog Input Voltage	\pm V _{SUPPLY}
Digital Input Voltage	(V+ + 0.3V) to (DGND - 0.3V)
ESD Rating	
Human Body Model (Per MIL-STD-883 Method 3015.7)	1.5kV

Operating Conditions

Temperature Range	0°C to +70°C
Supply Voltage Range (Typical)	\pm 4.5V to \pm 5.5V

CAUTION: Do not operate at or near the maximum ratings listed for extended periods of time. Exposure to such conditions may adversely impact product reliability and result in failures not covered by warranty.

NOTE:

- θ_{JA} is measured with the component mounted on a low effective thermal conductivity test board in free air. See Tech Brief TB379 for details.

Thermal Information

Thermal Resistance (Typical, Note 1)	θ_{JA} (°C/W)

NOTES:

- For the lowest crosstalk, and the best composite video performance, use $R_L \geq 1\text{k}\Omega$.
- Test Level: A. Production Tested; B. Typical or Established Limit Based on Characterization; C. Design Typical for Information Only.
- See AC Test Circuits (Figure 6 through Figure 9).
- Excludes D1/SER OUT which is a bidirectional terminal and thus falls under the higher Output Leakage limit.
- See "Typical Performance Curves" beginning on page 11 for more information.
- Parameters with MIN and/or MAX limits are 100% tested at +25°C, unless otherwise specified. Temperature limits established by characterization and are not production tested.

Application Information

HA456 Architecture

The HA456 video crosspoint switch consists of 64 switches in an 8x8 grid (see Figure 1). Each input is fully buffered and presents a constant input capacitance whether the input connects to one output or all 8 outputs. This yields consistent input termination impedances regardless of the switch configuration. The 8 matrix outputs are followed by 8 unity gain, wideband, tristatable buffers optimized for driving 400Ω and 5pF loads. The output disable function is useful for multiplexing two or more HA456s to create a larger input matrix (e.g., two multiplexed HA456s yield a 16x8 crosspoint).

The HA456 outputs can be disabled individually or collectively under software control. When disabled, an output enters a high-impedance state. In multichip parallel applications, the disable function prevents inactive outputs from loading lines driven by other devices. Disabling an unused output also reduces power consumption.

The HA456 outputs connect easily to two HFA1412 quad, gain-of-two buffers when 75Ω loads must be driven.

Power-On RESET

The HA456 has an internal power-on reset (POR) circuit that **disables all outputs at power-up**, and presets the switch matrix so that all outputs connect to IN0. In parallel mode, the desired switch state may be programmed before the outputs are enabled. In serial mode, all outputs are connected to GND each time they are enabled, so switch state programming must occur after the output is enabled.

Digital Interface

The desired switch state can be loaded using a 7-bit parallel interface mode or 32-bit serial interface mode (see Tables 1 through 3). All actions associated with the WR line occur on its rising edge. The same is true for the LATCH line if

EDGE/LEVEL = 1. Otherwise, the Slave Register updates asynchronously (while LATCH=0, if EDGE/LEVEL = 0). WR is logically AND'ed with CE and CE to allow active high or active low chip enable.

7-Bit Parallel Mode

In the parallel programming mode (SER/PAR = 0), the 7 control bits (A2:0 and D3:0) typically specify an output channel (A2:0) and the corresponding action to be taken (D3:0). Command codes are available to enable or disable all outputs, or individual outputs, as shown in Table 1. Each output has 4-bit Master and Slave Registers associated with it that hold the output's currently selected input address (defined by D3:0). The input address (if applicable) is loaded into the Master Register on the rising edge of WR. If the HA456 is in level mode, and if LATCH = 0 (asynchronous switching), then the input address flows through the transparent Slave Register and the output immediately switches to the new input. For synchronous switching on the rising edge of LATCH, strap the HA456 for edge mode, program all the desired switch connections, and then drive an inverted pulse on the LATCH input. Note: Operations defined by commands 1011 - 1111 occur asynchronously on the WR rising edge, without regard for the state of LATCH or EDGE/LEVEL.

32-Bit Serial Mode

In the serial programming mode, all master registers are loaded with data, making it unnecessary to specify an output address (A2:0). The input data format is D3-D0, starting with OUT0 and ending with OUT7 for 32 total bits (i.e., first bit shifted in is D3 for OUT0, and 32nd bit shifted in is D0 for OUT7). Only codes 0000 through 1010 are valid serial mode commands. Code 1010 disables an individual output, while code 1001 enables it. After data is shifted into the 32-bit Master Register, it transfers to the Slave Register on the rising edge of the LATCH line (Edge mode), or when LATCH = 0 (Level mode, see Figure 5).

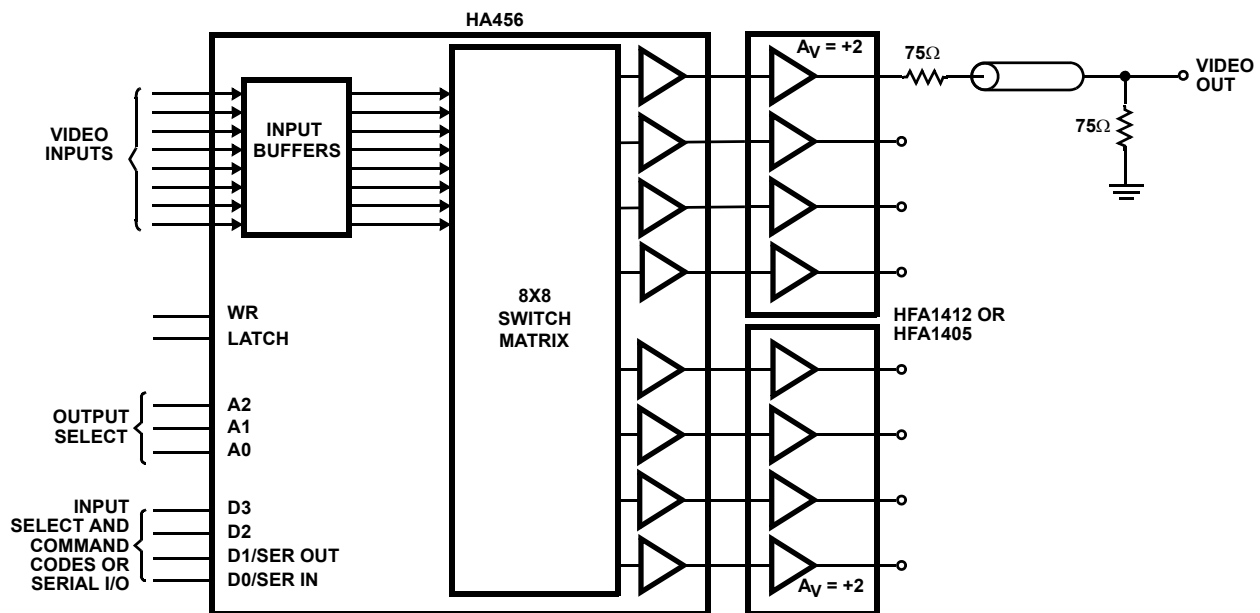

FIGURE 1. TYPICAL CABLE DRIVING APPLICATION

TABLE 1. PARALLEL INTERFACE COMMANDS

A2:0	D3:0	ACTION
Selects Output Being Programmed	0000 to 0111	Connect the input defined by D3:0 to the output selected by A2:0. Doesn't enable a disabled output.
	1000	Connect the output selected by A2:0 to GND. Doesn't enable a disabled output.
	1011	Asynchronously disable the single output selected by A2:0, and leave the Master Register unchanged.
	1100	Asynchronously enable the single output selected by A2:0, and leave the Master Register unchanged.
Address Inputs are Irrelevant for These Functions	1101	Asynchronously disable all outputs, and leave the Master Register unchanged.
	1110	Asynchronously enable all outputs, and leave the Master Register unchanged.
	1111	Send a Software "Latch" pulse to the Slave Register to load it from the Master Register, iff, the LATCH input = 1. If the LATCH input = 0, then this command is a NOP. The Master Register is unchanged by this command.
	1001 or 1010	Do not use these codes in the parallel programming mode. These codes are for serial programming only.

TABLE 2. SERIAL INTERFACE COMMANDS

D3:0	ACTION
0000 to 0111	Connect the output to the input channel defined by D3:0. Doesn't enable a disabled output.
1000	Connect the output to GND. Doesn't enable a disabled output.
1001	Enable the output and connect it to GND. The default power-up state is all outputs disabled, so use this code to enable outputs after power is applied, but before programming the switch configuration.
1010	Disable the output. The output is no longer associated with any input channel; the desired input must be redefined after re enabling the output.
1011 to 1111	Do not use these codes in the serial programming mode.

TABLE 3. DEFINITION OF DATA AND ADDRESS BIT FUNCTIONS

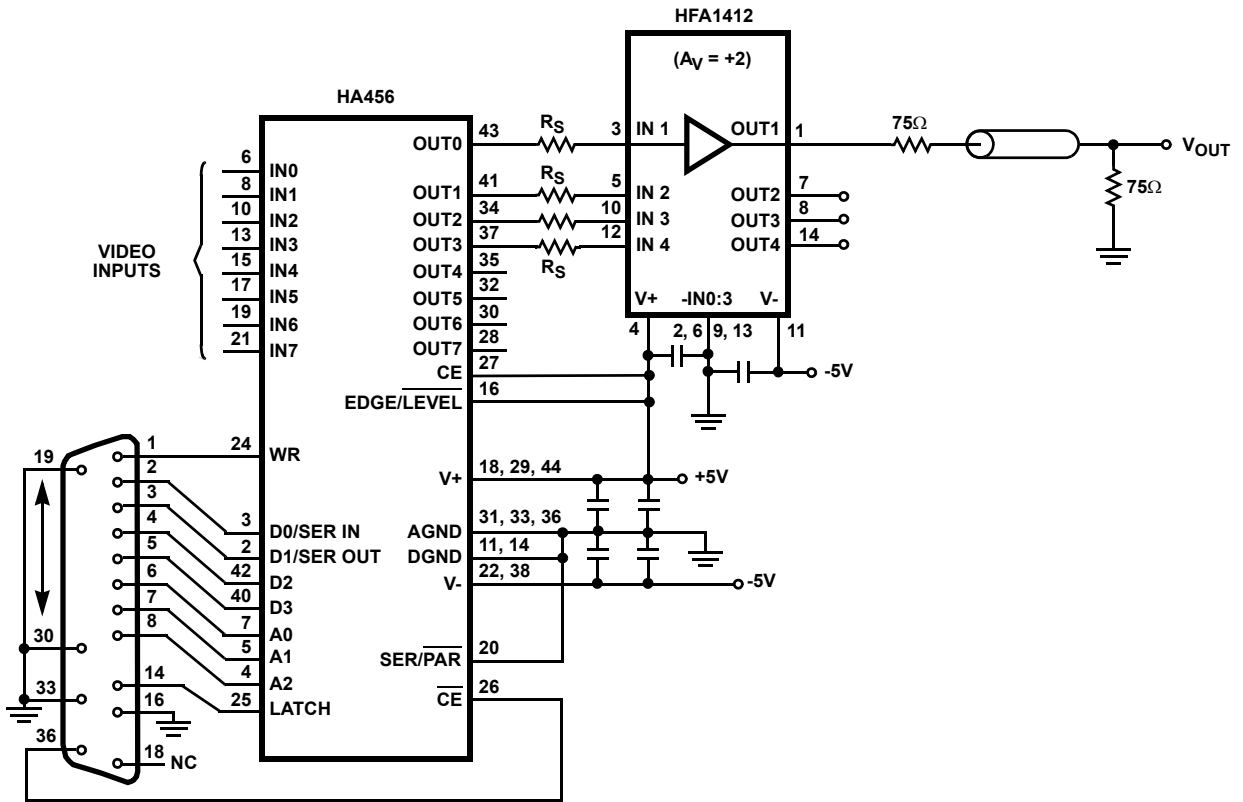

SER/PAR	D3	D2	D1	D0	A2:0	COMMENT
H	X	X	Serial Data Output	Serial Data Input	X	32-Bit Serial Mode
L	H	Parallel Data Input	Parallel Data Input	Parallel Data Input	Output Address	Parallel Mode; D2:0 define the command to be executed
L	L	Parallel Data Input	Parallel Data Input	Parallel Data Input	Output Address	Parallel Mode; D2:0 define the Input Channel

Figure 2 shows a typical application of the HA456 with HFA1412 quad, gain-of-two buffers at the outputs to drive 75Ω loads. This application shows the HA456 digital-switch control interface set up in the 7-bit parallel mode. The HA456 uses 7 data lines and 3 control lines (WR, $\overline{\text{CE}}$ and LATCH).

The input/output information is presented to the chip at A2:0 and D3:0 by a parallel printer port. The data is stored in the Master Registers on the rising edge of WR. When the LATCH line goes high, the switch configuration loads into the Slave Registers, and all 8 outputs reconfigure at the same time. Each 7-bit word updates only one output at a time.

If several outputs are to be updated, the data is individually loaded into the Master Registers. Then, a single LATCH pulse can reconfigure all channels simultaneously.

An IBM compatible PC loads the programming data into the HA456 via its parallel port (LPT1) using a simple BASIC program.

NOTE: All decoupling capacitors 0.1μF Ceramic (1 per supply pin). For lowest crosstalk, connect unused pins to GND use R_S to tune the overall output response.

NOTES:

8. Program the desired input to output combination (e.g., IN7 to OUT1).
9. Enable the selected output(s).
10. Drive the selected input with V_{IN} , and measure the -3dB frequency at the selected output (V_{OUT}).
11. Load all outputs with the desired R_L .
12. Disable all outputs.
13. Drive all inputs with V_{IN} and measure V_{OUT} at any output; isolation (in dB) = $-20\log_{10}(V_{OUT}/V_{IN})$.
14. Drive V_{IN} on one input which connects to one output (e.g., IN7 to OUT7).
15. Terminate all other inputs to GND.
16. Enable all outputs.
17. Measure V_{OUT} at any undriven output; crosstalk (in dB) = $20\log_{10}(V_{OUT}/V_{IN})$.
18. Terminate one input to GND, and connect that input to a single output (e.g., IN0 to OUT0).
19. Drive the other seven inputs with V_{IN} , and connect these active inputs to the remaining seven outputs.
20. Measure V_{OUT} at the quiescent output; crosstalk (in dB) = $20\log_{10}(V_{OUT}/V_{IN})$.

Typical Performance Curves $V_{SUPPLY} = \pm 5V$, $T_A = +25^\circ C$, $R_L = 400\Omega$, Unless Otherwise Specified.
