

ABSOLUTE MAXIMUM RATINGS

These are stress ratings only and functional operation of the device at these ratings or any other above those indicated in the operation sections to the specifications below is not implied.

V_{CC}	-0.3V to +7.0V
Input Voltage at Control and Driver Input (\overline{RE} , DE, and DI)	-0.3V to +7.0V
Receiver Output Voltage (RO)	-0.3V to ($V_{CC} + 0.3V$)
Driver Output Voltage (A and B)	$\pm 18V$
Receiver Input Voltage (A and B)	$\pm 18V$
Transient Voltage Pulse, through 100 Ω Figure 5	$\pm 70V$
Driver Output Current	$\pm 250mA$
Storage Temperature Range	-65°C to +150°C
Lead Temperature (soldering, 10s)	+300°C
Package Power Dissipation 8-Pin SO $\Theta_{JA} = 128.4^{\circ}C/W$ 14-Pin SO $\Theta_{JA} = 86^{\circ}C/W$	Maximum Junction Temperature = +150°C

NOTE:

3. Change in Magnitude of Differential Output Voltage and Change in Magnitude of Common Mode Output Voltage are the changes in output voltage when DI input changes state.
4. The hot swap feature disables the DE and \overline{RE} inputs for the first 10 μ s after power is applied. Following this time period these inputs are weakly pulled to their disabled state (low for DE, high for \overline{RE}) until the first transition, after which they become high impedance inputs.
5. The transceivers are put into shutdown by bringing \overline{RE} High and DE Low simultaneously for at least 600ns. If the control inputs are in this state for less than 50ns, the device is guaranteed to not enter shutdown. If the enable inputs are held in this state for at least 600ns the device is assured to be in shutdown. Note that the receiver and driver enable times increase significantly when coming out of shutdown.

PIN DESCRIPTIONS

PIN NUMBER	PIN NAME	TYPE	DESCRIPTION
1	RO	Out	Receiver Output. When \overline{RE} is low and if $(A-B) \geq -50\text{mV}$, RO is high. If $(A-B) \leq -200\text{mV}$, RO is Low.
2	\overline{RE}	In	Receiver Output Enable (Hot Swap). When \overline{RE} is low, RO is enabled. When \overline{RE} is High, RO is high impedance. When \overline{RE} is high and DE is low, shutdown mode is enabled.
3	DE	In	Driver Output Enable (Hot Swap). When DE is high, outputs are enabled. When DE is low, outputs are high impedance. When DE is low and \overline{RE} is high, shutdown mode is enabled.
4	DI	In	Driver Input. With DE high, a low level on DI forces non-Inverting output low and inverting output high. Similarly, a high level on DI forces non-Inverting output high and inverting output low.
5	GND	Pwr	Ground.
6	A	I/O	Non-Inverting Receiver Input and Non-Inverting Driver Output.
7	B	I/O	Inverting Receiver Input and Inverting Driver Output.
8	V_{CC}	Pwr	Power Supply Input. Bypass to ground with 0.1 μF capacitor.

PRODUCT DESCRIPTION

The XR33032/35/38 RS-485/422 devices are part of Exar's high performance serial interface product line. The analog bus pins can survive direct shorts up to $\pm 18V$, and are protected against ESD events up to $\pm 15kV$.

ENHANCED FAILSAFE

Standard RS-485 differential receivers will be in an indeterminate state whenever the analog bus pins are not being driven. The enhanced failsafe feature of the XR33032/35/38 family guarantees a logic-high receiver output when the receiver inputs are open, shorted, or when they are connected to a terminated transmission line with all drivers disabled. In a terminated bus with all transmitters disabled, the receivers' differential input voltage is pulled to 0V by the termination. The XR33032/35/38 family interprets 0V differential as a logic high with a minimum 50mV noise margin while maintaining compliance with the EIA/TIA-485 standard of $\pm 200mV$. Although the XR33032/35/38 family does not need failsafe biasing resistors, it can operate without issue if biasing is used.

RECEIVER INPUT FILTERING

XR33032 and XR33035 receivers incorporate internal filtering in addition to input hysteresis. This filtering enhances noise immunity by ignoring signals that do not meet a minimum pulse width of 30ns. Receiver propagation delay increases slightly due to this filtering. The high speed XR33038 device does not have this input filtering.

HOT-SWAP CAPABILITY

When V_{CC} is first applied the driver enable and receiver enable (DE and \overline{RE}) are held inactive for approximately 10 microseconds. During power ramp-up other system ICs may drive unpredictable values, or tristated lines may be influenced by stray capacitance. The hot-swap feature prevents these devices from driving any output signal until power has stabilized. After the initial 10 μs , the driver and receiver enable pins are weakly pulled to their disabled states (low for DE, high for \overline{RE}) until the first transition. After the first transition, the DE and \overline{RE} pins operate as high impedance inputs.

If circuit boards are inserted into an energized backplane (commonly called "live insertion" or "hot-swap") power may suddenly be applied to all circuits. Without the hot-swap capability, this situation could improperly enable the transceiver's driver or receiver, driving invalid data onto shared busses and possibly causing driver contention or device damage.

DRIVER OUTPUT PROTECTION

Two mechanisms prevent excessive output current and power dissipation caused by faults or by bus contention. First, a driver current limit on the output stage provides immediate protection against short circuits over the whole common-mode voltage range. Second, a thermal-shutdown circuit forces the driver outputs into a high-impedance state if junction temperature becomes excessive.

LINE LENGTH and TERMINATIONS

The RS-485/RS-422 standard covers line lengths up to 4000ft. Maximum achievable line length is a function of the data rate, cable characteristics and environmental noise. Termination prevents signal reflections by eliminating the impedance mismatches on a transmission line. Line termination is generally used if rise and fall times are shorter than the round-trip signal propagation time. Higher supply voltage will allow longer cables to be used.

±15kV ESD PROTECTION

ESD protection structures are incorporated on all pins to protect against electrostatic discharges encountered during handling, assembly and operation. The driver outputs and receiver inputs of the XR33032/35/38 have extra protection against static electricity. Exar uses state of the art structures to protect these pins against ESD of ±15kV without damage. The ESD structures withstand high ESD in all states: normal operation, shutdown and powered down. After an ESD event, the XR33032/35/38 keep operating without latch-up or damage.

ESD protection can be tested in various ways. The transmitter outputs and receiver inputs of the XR33032/35/38 are characterized for protection to the following limits:

- ±15kV using the Human Body Model
- ± 8kV Contact Discharge Model
- ±15kV Air-gap Discharge Model

IEC 61000-4-2

The IEC 61000-4-2 standard covers ESD testing and performance of finished equipment. However, it does not specifically refer to integrated circuits. The XR33032/35/38 family helps you design equipment to meet IEC 61000-4-2, without sacrificing board-space and cost for external ESD-protection components.

The major differences between tests done using the Human body model and IEC 61000-4-2 is a higher peak current in IEC 61000-4-2. Series resistance is lower in the IEC 61000-4-2 model. Hence, the ESD withstand voltage measured to IEC 61000-4-2 is generally lower than that of human body model.

The air-gap test involves approaching the device with a charged probe. The contact discharge method connects the probe to the device before the probe is energized.

256 TRANSCEIVERS ON THE BUS

The standard RS-485 receiver input impedance is 12k Ohms (1 unit load). A standard driver can drive up to 32 unit loads. The XR33032/35/38 transceivers have a 1/8th unit load receiver input impedance of 96kΩ, allowing up to 256 transceivers to be connected in parallel on a communication line. Any combination of these devices and other RS-485 transceivers up to a total of 32 unit loads may be connected to the line.

LOW POWER SHUTDOWN MODE

Low-power shutdown mode is initiated by bringing both \overline{RE} high and DE low simultaneously. While in shutdown devices draw less than 1μA of supply current. DE and \overline{RE} may be tied together and driven by a single control signal. Devices are guaranteed not to enter shutdown if \overline{RE} is high and DE is low for less than 50ns. If the inputs are in this state for at least 600ns, the parts will enter shutdown.

Enable times t_{ZH} and t_{ZL} apply when the part is not in low-power shutdown state. Enable times $t_{ZH(SHDN)}$ and $t_{ZL(SHDN)}$ apply when the parts are shutdown. The drivers and receivers take longer to become enabled from low-power shutdown $t_{ZH(SHDN)}$ and $t_{ZL(SHDN)}$ than from driver / receiver disable mode (t_{ZH} and t_{ZL}).

FUNCTION TABLES
TABLE 1: HALF DUPLEX 8 PIN

TRANSMITTING				
Inputs			Outputs	
\overline{RE}	DE	DI	A	B
X	1	1	1	0
X	1	0	0	1
0	0	X	High-Z	
1	0	X	Shutdown	

TABLE 2: HALF DUPLEX 8 PIN

RECEIVING			
Inputs			Output
\overline{RE}	DE	$V_A - V_B$	RO
0	X	$\geq -50\text{mV}$	1
0	X	$\leq -200\text{mV}$	0
0	X	Open/Shorted	1
1	1	X	High-Z
1	0	X	Shutdown

Note: Receiver inputs $-200\text{mV} \leq V_A - V_B \leq -50\text{mV}$ are considered indeterminate.
