Features

- Operating from V_{CC} = 2.4 V to 5.5 V
- Standby mode active low
- Output power: 3 W into 4 Ω and 1.75 W into 8 Ω with 10% THD+N max and 5 V power supply
- Output power: 2.3 W @ 5 V or 0.75 W @ 3 V into 4 Ω with 1% THD+N max

Datasheet - production data

- Output power: 1.4 W @ 5 V or 0.45 W @ 3 V into 8 Ω with 1% THD+N max
- Adjustable gain via external resistors
- Low current consumption 2 mA @ 3 V
- Efficiency: 88% typ.
- Signal to noise ratio: 85 dB typ.
- PSRR: 63 dB typ. @ 217 Hz with 6 dB gain
- PWM base frequency: 250 kHz
- Low pop & click noise
- Thermal shutdown protection
- Available in flip-chip 9 x 300 μm (Pb-free)

Applications

- Wearable
- Fitness and healthcare
- Cellular phone
- PDA

Description

The A21SP16 is a differential class-D BTL power amplifier. It is able to drive up to 2.3 W into a 4 Ω load and 1.4 W into a 8 Ω load at 5 V. It achieves outstanding efficiency (88% typ.) compared to classical Class-AB audio amps.

The gain of the device can be controlled via two external gain-setting resistors. Pop & click reduction circuitry provides low on/off switch noise while allowing the device to start within 5 ms. A standby function (active low) allows the reduction of current consumption to 10 nA typ.

1 Absolute maximum ratings

Table 2.	Absolute	maximum	ratings
----------	----------	---------	---------

Symbol	Parameter	Value	Unit
V _{CC}	Supply voltage ^{(1), (2)}	6	V
V _{in}	Input voltage ⁽³⁾	GND to V _{CC}	V
T _{oper}	Operating free-air temperature range	-40 to + 85	°C
T _{stg}	Storage temperature	-65 to +150	°C
Тj	Maximum junction temperature	150	°C
R _{thja}	Thermal resistance junction to ambient ⁽⁴⁾	200	°C/W
P _{diss}	Power dissipation	Internally limited ⁽⁵⁾	
ESD	Human body model	2	kV
ESD	Machine model	200	V
Latch-up	Latch-up immunity	200	mA
V _{STBY}	Standby pin voltage maximum voltage ⁽⁶⁾	GND to V _{CC}	V
	Lead temperature (soldering, 10 sec)	260	°C

 Caution: This device is not protected in the event of abnormal operating conditions, such as for example, short-circuiting between any one output pin and ground, between any one output pin and V_{CC}, and between individual output pins.

2. All voltage values are measured with respect to the ground pin.

- 3. The magnitude of the input signal must never exceed V $_{CC}$ + 0.3V / GND 0.3V.
- 4. The device is protected in case of over temperature by a thermal shutdown active @ 150°C.
- 5. Exceeding the power derating curves during a long period causes abnormal operation.
- 6. The magnitude of the standby signal must never exceed V_{CC} + 0.3V / GND 0.3V.

Table 3. Operating conditions

Symbol	Parameter	Value	Unit
V _{CC}	Supply voltage ⁽¹⁾	2.4 to 5.5	V
V _{IC}	Common mode input voltage range ⁽²⁾	0.5 to V _{CC} - 0.8	V
V _{STBY}	Standby voltage input: ⁽³⁾ Device ON Device OFF	$\begin{array}{l} 1.4 \leq \ V_{STBY} \leq \ V_{CC} \\ \text{GND} \ \leq \ V_{STBY} \ \leq \ 0.4 \\ (4) \end{array}$	V
RL	Load resistor	≥ 4	Ω
R _{thja}	Thermal resistance junction to ambient ⁽⁵⁾	90	°C/W

1. For V_{CC} from 2.4V to 2.5V, the operating temperature range is reduced to 0°C \leq T_{amb} \leq 70°C.

2. For V_{CC} from 2.4V to 2.5V, the common mode input range must be set at $V_{CC}/2.$

3. Without any signal on $V_{\mbox{\scriptsize STBY}}$, the device will be in standby.

4. Minimum current consumption is obtained when V_{STBY} = GND.

5. With heat sink surface = 125 mm².

2 Application component information

Component	Functional description					
Cs	Bypass supply capacitor. Install as close as possible to the A21SP16 to minimize high-frequency ripple. A 100nF ceramic capacitor should be added to enhance the power supply filtering at high frequency.					
R _{in}	Input resistor to program the A21SP16 differential gain (gain = 300 k Ω/R_{in} with R_{in} in $k\Omega$).					
Input capacitor	Due to common mode feedback, these input capacitors are optional. However, they can be added to form with R_{in} a 1st order high pass filter with -3dB cut-off frequency = $1/(2^*\pi^*R_{in}^*C_{in})$.

4 Electrical characteristic curves

The graphs included in this section use the following abbreviations:

- R_L + 15 μ H or 30 μ H = pure resistor + very low series resistance inductor
- Filter = LC output filter (1 μ F + 30 μ H for 4 Ω and 0.5 μ F + 60 μ H for 8 Ω)
- All measurements done with $C_{s1} = 1\mu F$ and $C_{s2} = 100 nF$ except for PSRR where Cs1 is removed.

5 Application information

5.1 Differential configuration principle

The A21SP16 is a monolithic fully-differential input/output class D power amplifier. The A21SP16 also includes a common-mode feedback loop that controls the output bias value to average it at $V_{CC}/2$ for any DC common mode input voltage. This allows the device to always have a maximum output voltage swing, and by consequence, maximizes the output power. Moreover, as the load is connected differentially compared to a single-ended topology, the output is four times higher for the same power supply voltage.

The advantages of a full-differential amplifier are:

- High PSRR (power supply rejection ratio).
- High common mode noise rejection.
- Virtually zero pop without additional circuitry, giving a faster start-up time compared to conventional single-ended input amplifiers.
- Easier interfacing with differential output audio DAC.
- No input coupling capacitors required due to common mode feedback loop.

The main disadvantage is:

• As the differential function is directly linked to external resistor mismatching, paying particular attention to this mismatching is mandatory in order to obtain the best performance from the amplifier.

5.2 Gain in typical application schematic

Typical differential applications are shown in Figure 1 on page 4.

In the flat region of the frequency-response curve (no input coupling capacitor effect), the differential gain is expressed by the relation:

$$A_{V_{diff}} = \frac{Out^{+} - Out^{-}}{In^{+} - In^{-}} = \frac{300}{R_{in}}$$

with R_{in} expressed in k Ω .

Due to the tolerance of the internal 150 k Ω feedback resistor, the differential gain will be in the range (no tolerance on R_{in}):

$$\frac{273}{R_{in}} \leq \ A_{V_{diff}} \leq \ \frac{327}{R_{in}}$$

As explained previously, the common mode feedback loop allows the output DC bias voltage to be averaged at $V_{CC}/2$ for any DC common mode bias input voltage.

However, due to V_{icm} limitation in the input stage (see *Table 3: Operating conditions on page 3*), the common mode feedback loop can ensure its role only within a defined range. This range depends upon the values of V_{CC} and R_{in} (A_{Vdiff}). To have a good estimation of the V_{icm} value, we can apply this formula (no tolerance on R_{in}):

$$V_{icm} = \frac{V_{CC} \times R_{in} + 2 \times V_{IC} \times 150 k\Omega}{2 \times (R_{in} + 150 k\Omega)} \qquad (V)$$

with

$$V_{IC} = \frac{In^+ + In^-}{2} \quad (V)$$

and the result of the calculation must be in the range:

 $0.5V \le V_{icm} \le V_{CC} - 0.8V$

Due to the +/-9% tolerance on the 150k Ω resistor, it's also important to check V_{icm} in these conditions:

$$\frac{\mathsf{V}_{\mathsf{CC}} \times \mathsf{R}_{\mathsf{in}} + 2 \times \mathsf{V}_{\mathsf{IC}} \times 136.5 \mathrm{k}\Omega}{2 \times (\mathsf{R}_{\mathsf{in}} + 136.5 \mathrm{k}\Omega)} \leq \mathsf{V}_{\mathsf{icm}} \leq \frac{\mathsf{V}_{\mathsf{CC}} \times \mathsf{R}_{\mathsf{in}} + 2 \times \mathsf{V}_{\mathsf{IC}} \times 163.5 \mathrm{k}\Omega}{2 \times (\mathsf{R}_{\mathsf{in}} + 163.5 \mathrm{k}\Omega)}$$

If the result of V_{icm} calculation is not in the previous range, input coupling capacitors must be used (with V_{CC} from 2.4 V to 2.5 V, input coupling capacitors are mandatory).

For example:

With V_{CC} = 3 V, R_{in} = 150 k Ω and V_{IC} = 2.5 V, we typically find V_{icm} = 2 V and this is lower than 3V - 0.8 V = 2.2 V. With 136.5 k Ω we find 1.97 V, and with 163.5 k Ω we have 2.02 V. So, no input coupling capacitors are required.

5.4 Low frequency response

If a low frequency bandwidth limitation is requested, it is possible to use input coupling capacitors.

In the low frequency region, C_{in} (input coupling capacitor) starts to have an effect. C_{in} forms, with R_{in} , a first order high-pass filter with a -3dB cut-off frequency:

$$F_{CL} = \frac{1}{2\pi \times R_{in} \times C_{in}} \qquad (Hz)$$

So, for a desired cut-off frequency we can calculate C_{in},

$$C_{in} = \frac{1}{2\pi \times R_{in} \times F_{CL}} \qquad (F)$$

with R_{in} in Ω and F_{CL} in Hz.

DocID026037 Rev 2

5.5 Decoupling of the circuit

A power supply capacitor, referred to as $C_{S_{.}}$ is needed to correctly bypass the A21SP16.

The A21SP16 has a typical switching frequency at 250 kHz and output fall and rise time about 5 ns. Due to these very fast transients, careful decoupling is mandatory.

A 1 μ F ceramic capacitor is enough, but it must be located very close to the A21SP16 in order to avoid any extra parasitic inductance created an overly long track wire. In relation with dl/dt, this parasitic inductance introduces an overvoltage that decreases the global efficiency and, if it is too high, may cause a breakdown of the device.

In addition, even if a ceramic capacitor has an adequate high frequency ESR value, its current capability is also important. A 0603 size is a good compromise, particularly when a 4 Ω load is used.

Another important parameter is the rated voltage of the capacitor. A 1 μ F/6.3 V capacitor used at 5 V, loses about 50% of its value. In fact, with a 5 V power supply voltage, the decoupling value is about 0.5 μ F instead of 1 μ F. As C_S has particular influence on the THD+N in the medium-high frequency region, this capacitor variation becomes decisive. In addition, less decoupling means higher overshoots, which can be problematic if they reach the power supply AMR value (6 V).

5.6 Wake-up time (t_{WU})

When the standby is released to set the device ON, there is a wait of about 5 ms. The A21SP16 has an internal digital delay that mutes the outputs and releases them after this time in order to avoid any pop noise.

5.7 Shutdown time (t_{STBY})

When the standby command is set, the time required to put the two output stages into high impedance and to put the internal circuitry in shutdown mode, is about 5 ms. This time is used to decrease the gain and avoid any pop noise during shutdown.

5.8 Consumption in shutdown mode

Between the shutdown pin and GND there is an internal 300 k Ω resistor. This resistor forces the A21SP16 to be in standby mode when the standby input pin is left floating.

However, this resistor also introduces additional power consumption if the shutdown pin voltage is not 0 V.

For example, with a 0.4 V standby voltage pin, *Table 3: Operating conditions on page 3*, shows that you must add 0.4 V/300 k Ω = 1.3 µA in typical (0.4 V/273 k Ω = 1.46 µA in maximum) to the shutdown current specified in *Table 5 on page 5*.

5.9 Single-ended input configuration

It is possible to use the A21SP16 in a single-ended input configuration. However, input coupling capacitors are needed in this configuration. The schematic in *Figure 61* shows a single-ended input typical application.

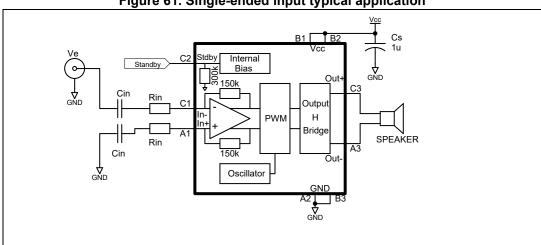

Figure 61. Single-ended input typical application

All formulas are identical except for the gain (with R_{in} in $\mathsf{k}\Omega$):

$$A_{V_{single}} = \frac{V_{e}}{Out^{+} - Out^{-}} = \frac{300}{R_{in}}$$

And, due to the internal resistor tolerance we have:

$$\frac{273}{R_{in}} \le A_{V_{single}} \le \frac{327}{R_{in}}$$

In the event that multiple single-ended inputs are summed, it is important that the impedance on both A21SP16 inputs (In^- and In^+) are equal.

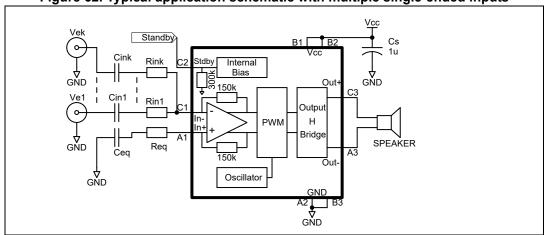

Figure 62. Typical application schematic with multiple single-ended inputs

We have the following equations:

$$Out^{+} - Out^{-} = V_{e1} \times \frac{300}{R_{in1}} + \dots + V_{ek} \times \frac{300}{R_{ink}}$$
(V)
$$C_{eq} = \sum_{j=1}^{k} C_{inj}$$
$$C_{inj} = \frac{1}{2 \times \pi \times R_{inj} \times F_{CLj}}$$
(F)
$$R_{eq} = \frac{1}{\sum_{i=1}^{k} \frac{1}{R_{inj}}}$$

In general, for mixed situations (single-ended and differential inputs), it is best to use the same rule, that is, to equalize impedance on both A21SP16 inputs.

5.10 Output filter considerations

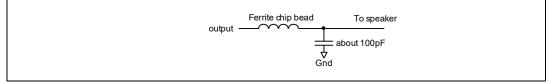

The A21SP16 is designed to operate without an output filter. However, due to very sharp transients on the A21SP16 output, EMI radiated emissions may cause some standard compliance issues.

These EMI standard compliance issues can appear if the distance between the A21SP16 outputs and loudspeaker terminal is long (typically more than 50 mm, or 100 mm in both directions, to the speaker terminals). As the PCB layout and internal equipment device are different for each configuration, it is difficult to provide a one-size-fits-all solution.

However, to decrease the probability of EMI issues, there are several simple rules to follow:

- Reduce, as much as possible, the distance between the A21SP16 output pins and the speaker terminals.
- Use ground planes for "shielding" sensitive wires.
- Place, as close as possible to the A21SP16 and in series with each output, a ferrite bead with a rated current at minimum 2 A and impedance greater than 50 Ω at frequencies above 30 MHz. If, after testing, these ferrite beads are not necessary, replace them by a short-circuit. Murata BLM18EG221SN1 or BLM18EG121SN1 are possible examples of devices you can use.
- Allow enough footprint to place, if necessary, a capacitor to short perturbations to ground (see the schematics in *Figure 63*).

Figure 63. Method for shorting pertubations to ground

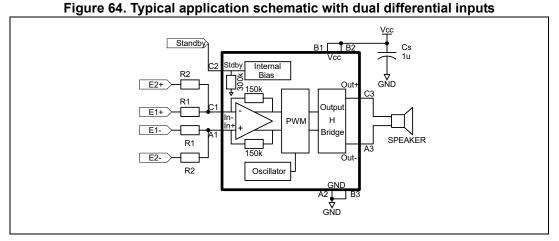

In the case where the distance between the A21SP16 outputs and speaker terminals is high, it is possible to have low frequency EMI issues due to the fact that the typical operating frequency is 250 kHz. In this configuration, we recommend using an output filter (as shown

in *Figure 1: Typical application schematics on page 4*). It should be placed as close as possible to the device.

5.11 Different examples with summed inputs

Example 1: Dual differential inputs

With $(R_i \text{ in } k\Omega)$:

$$A_{V_{1}} = \frac{Out^{+} - Out^{-}}{E_{1}^{+} - E_{1}^{-}} = \frac{300}{R_{1}}$$
$$A_{V_{2}} = \frac{Out^{+} - Out^{-}}{E_{2}^{+} - E_{2}^{-}} = \frac{300}{R_{2}}$$

$$0.5V \le \frac{V_{CC} \times R_1 \times R_2 + 300 \times (V_{IC1} \times R_2 + V_{IC2} \times R_1)}{300 \times (R_1 + R_2) + 2 \times R_1 \times R_2} \le V_{CC} - 0.8V$$
$$V_{IC_1} = \frac{E_1^+ + E_1^-}{2} \text{ and } V_{IC_2} = \frac{E_2^+ + E_2^-}{2}$$

Example 2: One differential input plus one single-ended input

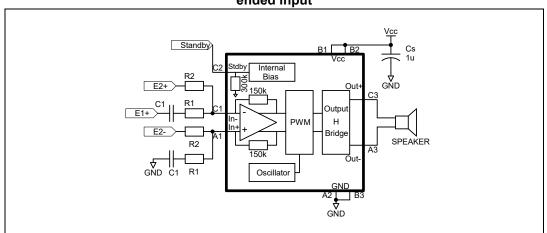

Figure 65. Typical application schematic with one differential input plus one singleended input

With (R_i in k Ω):

$$A_{V_{1}} = \frac{Out^{+} - Out^{-}}{E_{1}^{+}} = \frac{300}{R_{1}}$$
$$A_{V_{2}} = \frac{Out^{+} - Out^{-}}{E_{2}^{+} - E_{2}^{-}} = \frac{300}{R_{2}}$$
$$C_{1} = \frac{1}{2\pi \times R_{1} \times F_{CL}} \quad (F)$$
