

MAX77826

Power Management IC

General Description

The MAX77826 is a subpower management IC for the latest 3G/4G smartphones and tablets. The MAX77826 contains a high-efficiency BUCK regulator, a BUCK BOOST regulator and 15 LDOs to power up peripherals. The MAX77826 also provides power on/off control logic and an I²C serial interface to program individual regulator output voltages and on/off control for complete flexibility.

The linear regulators support a remote cap feature and provide greater than 70dB PSRR and less than 45 μ V_{RMS} noise.

The MAX77826 features I²C-compatible, 2-wire serial interface that comprises a bidirectional serial data line (SDA) and a serial clock line (SCL). The MAX77826 supports SCL clock rates up to 3.4MHz.

Applications

- GSM, GPRS, EDGE, CDMA WCDMA, and LTE Smartphones and Tablets

Ordering Information appears at end of data sheet.

Benefits and Features

- Compact Total Solution Size Allows More Peripheral Devices in Smartphones and Tablets
 - 3A High-Efficiency BUCK Regulator
 - DVS (Dynamic Voltage Scaling) Through HS I²C
 - $\pm 1\%$ (typ) Output Voltage DC Accuracy
 - Low Power Mode
 - 2A BUCK BOOST Regulator
 - 15 Linear Regulators with Remote Cap
 - 3 NMOS LDOs (V_{OUT} Range: 0.6V to 2.1875V with 12.5mV Step)
 - 1 x 150mA
 - 1 x 450mA
 - 1 x 600mA
 - 6 PMOSLV LDOs (V_{OUT} Range: 0.8V to 3.975V with 25mV Step)
 - 3 x 150mA
 - 3 x 300mA
 - 6 PMOSLS LDOs (V_{OUT} Range: 0.8V to 3.975V with 25mV Step)
 - 3 x 150mA
 - 3 x 300mA
 - $\pm 1.5\%$ Typical Output Voltage DC Accuracy
 - 70dB PSRR at 1kHz
 - Low Power Mode with 2 μ A (typ) for all LDOs
- Simple Management of Power-Up/Down Sequence, Output Voltage Setting, and Fault Detection
 - High-Speed (Up to 3.4MHz) I²C Serial Interface

Absolute Maximum Ratings

SYS, V _{IO} , INL1, INL2, INL3, INL4, INL5 to GND	-0.3V to +6.0V	LDO1, LDO2 to GND	-0.3V to (V _{INL1} + 0.3V)
INB to PGND	-0.3V to +6.0V	LDO3 to GND	-0.3V to (V _{INL2} + 0.3V)
INBB, OUTBB to PGND	-0.3V to +6.0V	LDO4, LDO5, LDO6, LDO7, LDO8, LDO9 to GND	-0.3V to (V _{INL3} + 0.3V)
PGND, PGND to GND	-0.3V to +0.3V	LDO10, LDO11 to GND	-0.3V to (V _{INL4} + 0.3V)
IRQB, CE, SDA, SCL to GND	-0.3V to (V _{VIO} + 0.3V)	LDO12, LDO13, LDO14, LDO15 to GND	-0.3V to (V _{INL5} + 0.3V)
FB_B, ENBB, ENB, ENL12, REFBYP to GND	-0.3V to (V _{SYS} + 0.3V)	LXB Continuous RMS Current (Note 1)	3A
FB_BB to PGND	-0.3V to (V _{OUTBB} + 0.3V)	LXBB1/LXBB2 Continuous RMS Current (Note 1)	3.3A
LXB to PGND	-0.3V to (V _{INB} + 0.3V)	Operating Temperature Range	-40°C to +85°C
LXBB1 to PGND	-0.3V to (V _{INBB} + 0.3V)	Junction Temperature	+150°C
LXBB2 to PGND	-0.3V to (V _{OUTBB} + 0.3V)	Storage Temperature Range	-65°C to +150°C
		Soldering Temperature (reflow)	+260°C

Note 1: LX_ node has internal clamp diodes to PGND_ and INB_. Applications that give forward bias to these diodes should ensure that the total power loss does not exceed IC's package power dissipation limits.

Package Thermal Characteristics (Note 2)

WLP
Junction-to-Ambient Thermal Resistance (θ_{JA})37°C/W

Note 2: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

General Electrical Characteristics

(V_{SYS} = V_{IN_} = +3.7V, V_{IO} = 1.8V, T_A = -40°C to +85°C, unless otherwise noted.)

VPARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS
Shutdown Supply Current	I _{SHDN_SYS}	CE = low		2.5	10	μA
Standby Current	I _{Q_SYS}	CE = high and all regulators are off		35		μA
Shutdown V _{IO} Current	I _{SHDN_VIO}	All regulators are off		0		μA
No Load Supply Current 1	I _{NO_LOAD1}	BUCK is on in normal mode (no switching)		60		μA
No Load Supply Current 2	I _{NO_LOAD2}	BUCK and BUCK BOOST are on in normal mode (no switching)		120		μA

Output Active Discharge Resistance	Output disabled, resistance from FB_B to PGNDB			100		Ω
LX Leakage	$V_{LXB} = 5.5V$ or 0V	$T_A = +25^\circ C$	-1	0.1	+1	μA
		$T_A = +85^\circ C$		1		
POWER-OK COMPARATOR						
Output POK Trip Level	V_{OUT} POK rising threshold			90		%
Output POK Hysteresis	V_{OUT} when V _{POK} switches			5		%

BUCK BOOST Electrical Characteristics

($V_{INBB} = +3.7V$, $V_{OUTBB} = +3.5V$, $T_A = -40^{\circ}C$ to $+85^{\circ}C$, typical values are at $T_A = +25^{\circ}C$, unless otherwise noted.) (Note 5)

PARAMETER	CONDITIONS		MIN	TYP	MAX	UNITS
GENERAL						
Operating Input Voltage Range	Supplied from V_{SYS}		2.6		5.5	V
Shutdown Supply Current	$V_{INBB} = 5.5V$, $V_{OUTBB} = 0V$	$T_A = +25^{\circ}C$		0.01		μA
		$T_A = +85^{\circ}C$		1		
Input Supply Current	Enabled, no load	HSKIP mode (no switching)		60		μA
		FPWM mode (switching)		9		mA
Active Discharge Resistance				100		Ω
Thermal Shutdown	T_A rising, $20^{\circ}C$ hysteresis			+165		$^{\circ}C$
H-BRIDGE						
Maximum Output Current (Note 6)	$V_{INBB} = 3.0V$, $V_{OUTBB} = 3.5V$		2000			mA
	$V_{INBB} = 2.6V$, $V_{OUTBB} = 3.5V$		1500			
Default Output Voltage	No load, $BB_VOUT[6:0] = 0x48$			3.5		V
Output Voltage Accuracy	$BB_VOUT[6:0] = 0x48$, no load	PWM mode	-1.0		+1.0	%
		HSKIP mode $T_A = +25^{\circ}C$	-1.0		+4.0	
Output Voltage Range	I^2C programmable (12.5mV step)		2.6		4.1875	V
Line Regulation	$V_{INBB} = 2.6V$ to $5.5V$			0.200		%/V
Load Regulation (Note 3)	$V_{OUTBB} = 3.5V$			0.125		%/A
Transient Load Response, V_{DROOP} (Note 3)	$V_{INBB} = 3.8V$, $V_{OUTBB} = 3.5V$, I_{OUT} changes from 10mA to 1A in 10 μs , $C_{OUT_ACTUAL} = 47\mu F$, $L = 1\mu H$			-100		mV
Output Overvoltage Threshold	With respect to V_{OUTBB}	$BB_OVP_TH[1:0] = 01b$		110		%
		$BB_OVP_TH[1:0] = 10b$		115		
		$BB_OVP_TH[1:0] = 11b$ (default)		120		
Switching Frequency	2-phase BUCK or BOOST mode		1.6	1.8	2.0	MHz
	3-phase mode			0.9		
LXBB1, LXBB2 Leakage Current	$V_{LXBB1/2} = 0V$ or $5.5V$, $V_{OUTBB} = 5.5V$, $V_{SYS} =$ $V_{INBB} = 5.5V$	$T_A = +25^{\circ}C$		0.1	1	μA
		$T_A = +85^{\circ}C$		0.2		
LXBB1/2 Current Limit			3.5	4.5	5.5	A
PMOS On-Resistance	$I_{LXBB} = 100mA$, per switch			65		m Ω
NMOS On-Resistance	$I_{LXBB} = 100mA$, per switch			55		m Ω

BUCK BOOST Electrical Characteristics (continued)(V_{INBB} = +3.7V, V_{OUTBB} = +3.5V, T_A = -40°C to +85°C, typical values are at T_A = +25°C, unless otherwise noted.) (Note 5)

PARAMETER	CONDITIONS	MIN	TYP	MAX	UNITS
Minimum Effective Output Capacitance	0μA < I _{OUT} < 2000mA		16		μF
Turn-On Delay Time	From ENBB asserting to LXBB Switching with bias on		6		μs
Soft-Start Time	V _{OUTBB} = 3.5V, I _{OUT} = 10mA		40		μs
POWER-OK COMPARATOR					
Output POK Trip Level	V _{OUTBB} POK rising threshold		80		%
Output POK Hysteresis	V _{OUT} when V _{POK} switches		5		%

LDO Electrical Characteristics

LDO NO.	TYPE	V _{OUT} RANGE (V)	STEP SIZE (mV)	I _{OUT} (max, mA)	DEFAULT V _{OUT} (V)	DEFAULT ON/OFF	INPUT PIN	C _{OUT} (μF)
1	NMOS	0.6–2.1875	12.5	600	1.0	Off	INL1	4.7

Note 3: Guaranteed by design. Not production tested.**Note 4:** 100% production tested at T_A = +25°C, limits over the operating range are guaranteed by design.**Note 5:** Limits are 100% production tested at T_A = +25°C. Limits over the operating temperature range are guaranteed through correlation using statistical quality control methods.**Note 6:** The maximum output current spec is not directly tested. Instead, it is guaranteed by LX NMOS current limit test.**Note 7:** For NMOS LDOs, V_{SYS} must be at least 1.5V above V_{OUT} (V_{SYS} ≥ V_{OUT} + 1.5V).**Note 8:** The maximum output current is guaranteed by the output voltage accuracy tests.**Note 9:** For stability, guaranteed by design and not production tested.**Note 10:** There is an n-channel MOSFET in series with the output active discharge resistance. This NMOS requires V_{SYS} > 1.2V to be enhanced.

Pin Configurations

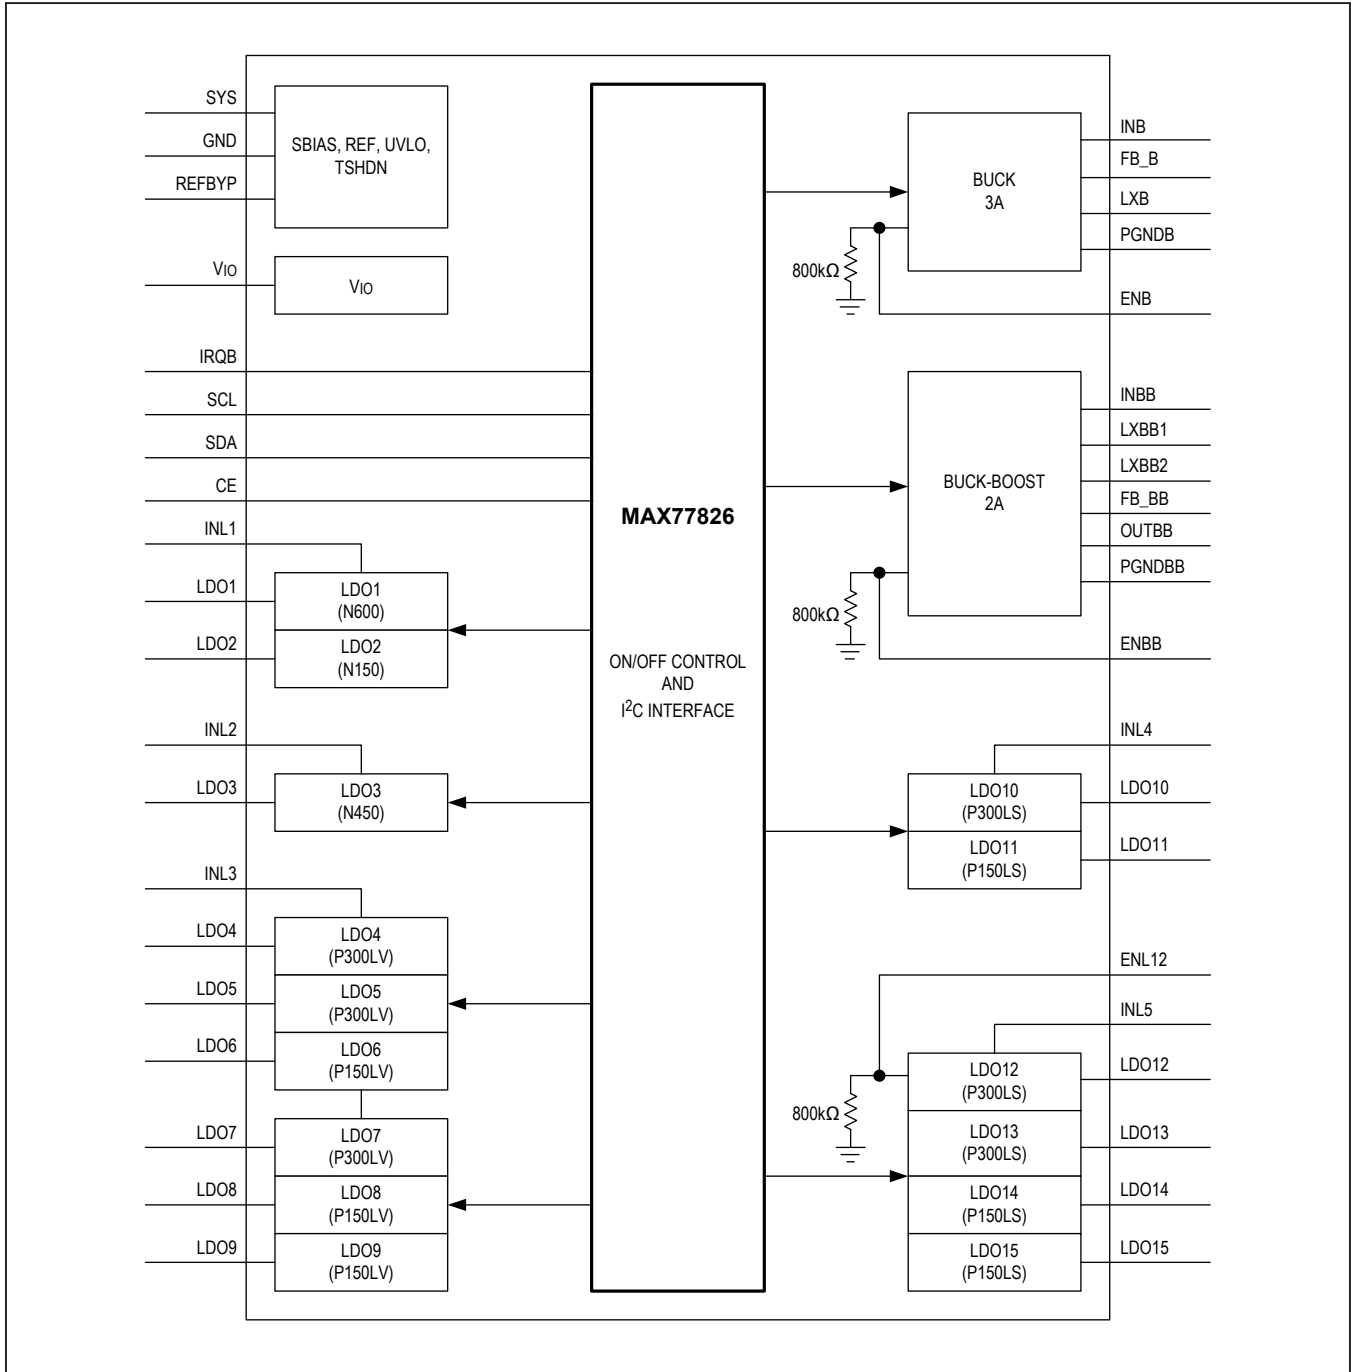

Pin Description

PIN	NAME	FUNCTION
C4	CE	Active-High Chip Enable Input. When CE = high (standby), the I ² C interface is enabled and regulators are ready to be turned on. When CE = low (shutdown), all regulators are turned off and all Type-O registers are reset to their POR default values.
D5	ENB	Active-High BUCK External Enable Input. An 800kΩ internal pull-down resistance to the GND. If this pin is not used, leave it floating.
E6	ENBB	Active-High BUCK BOOST External Enable Input. An 800kΩ internal pulldown resistance to the GND. If this pin is not used, leave it unconnected.
E4	ENL12	Active-High LDO12 External Enable Input. An 800kΩ internal pulldown resistance to the GND. If this pin is not used, leave it unconnected.
B3	FB_B	BUCK Output Voltage Feedback
E5	FB_BB	BUCK BOOST Output Voltage Feedback
E7	GND	Ground
A1, A2	INB	BUCK Input. Bypass to PGNDB with a 10μF capacitor.
F7, G7	INBB	BUCK BOOST Input

Pin Description (continued)

PIN	NAME	FUNCTION
B4	INL1	Input for LDO1 and 2. Bypass to GND with a 4.7 μ F capacitor.
B5	INL2	Input for LDO3. Bypass to GND with a 1 μ F capacitor.
C7	INL3	Input for LDO4, 5, 6, 7, 8, and 9. Bypass to GND with a 4.7 μ F capacitor.
F2	INL4	Input for LDO10 and 11. Bypass to GND with a 4.7 μ F capacitor.
F1	INL5	Input for LDO12, 13, 14, and 15. Bypass to GND with a 4.7 μ F capacitor.
E3	IRQB	Interrupt Output. A 100k Ω external pullup resistor to V _{IO} is required.
B1, B2	LXB	BUCK Switching Node
F6, G6	LXBB1	BUCK BOOST Switching Node 1
F4, G4	LXBB2	BUCK BOOST Switching Node 2
A4	LDO1	LDO1 (600mA NMOS) Output. Bypass to GND with a 4.7 μ F capacitor.
C6	LDO2	LDO2 (150mA NMOS) Output. Bypass to GND with a 1 μ F capacitor.
A5	LDO3	LDO3 (450mA NMOS) Output. Bypass to GND with a 4.7 μ F capacitor.
D7	LDO4	LDO4 (300mA PMOSLV) Output. Bypass to GND with a 4.7 μ F capacitor.
B7	LDO5	LDO5 (300mA PMOSLV) Output. Bypass to GND with a 4.7 μ F capacitor.
A7	LDO6	LDO6 (150mA PMOSLV) Output. Bypass to GND with a 2.2 μ F capacitor.
A6	LDO7	LDO7 (300mA PMOSLV) Output. Bypass to GND with a 4.7 μ F capacitor.
B6	LDO8	LDO8 (150mA PMOSLV) Output. Bypass to GND with a 2.2 μ F capacitor.
D6	LDO9	LDO9 (150mA PMOSLV) Output. Bypass to GND with a 2.2 μ F capacitor.
G1	LDO10	LDO10 (300mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
G2	LDO11	LDO11 (150mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
D1	LDO12	LDO12 (300mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
E1	LDO13	LDO13 (300mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
E2	LDO14	LDO14 (150mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
D2	LDO15	LDO15 (150mA PMOSLS) Output. Bypass to GND with a 2.2 μ F capacitor.
F3, G3	OUTBB	BUCK BOOST Output
C1, C2	PGNDB	BUCK Power GND
F5, G5	PGNDBB	BUCK BOOST Power GND
C5	REFBYP	LDO Reference Bypass Node. Connect a 0.1 μ F Cap to GND.
D4	SCL	I ² C Clock Input. High Impedance in Off State. A 1.5k Ω –2.2k Ω of pullup resistor to V _{IO} is required.
D3	SDA	I ² C Data I/O. High Impedance in Off State. A 1.5k Ω –2.2k Ω of pullup resistor to V _{IO} is required.
A3	SYS	System (Battery) Voltage Input. Bypass to GND with a 1 μ F capacitor.
C3	V _{IO}	IO Supply Voltage Input. Bypass to GND with a 0.1 μ F capacitor.

Block Diagram

Detailed Description

Top System Management

System Faults

The MAX77826 monitors the system for the following faults: global thermal, local thermal shutdown, and under-voltage lockout.

Global Thermal Fault

The MAX77826 has a centralized thermal protection circuit which monitors temperature on the die. If the die temperature exceeds $+165^{\circ}\text{C}$ (T_{SHDN}), a thermal shutdown event initiates, and the MAX77826 enters its global shutdown state.

In addition to the $+165^{\circ}\text{C}$ threshold, there are two additional comparators that trip at $+120^{\circ}\text{C}$ and $+140^{\circ}\text{C}$. Interrupts are generated in the event the die temperature reaches $+120^{\circ}\text{C}$ or $+140^{\circ}\text{C}$.

There is a 15°C thermal hysteresis. After the thermal shutdown, if the die temperature reduces by 15°C , the thermal shutdown bus deasserts.

Local Thermal Shutdown

If any of the BUCK BOOST or LDOs reach the thermal shutdown threshold, the MAX77826 shuts down the corresponding block locally. If the temperature goes below a threshold, that block goes back to normal operation.

Undervoltage Lockout

When V_{SYS} falls below $V_{\text{UVLO_F}}$ (typ 2.05V), the MAX77826 enters its undervoltage lockout (UVLO) mode. UVLO forces the MAX77826 to a dormant state until the source voltage is high enough to allow the MAX77826 to be securely functional. I²C does not function and the Type-O register contents are reset to their default values in UVLO mode. UVLO rising threshold is set to 2.5V by an OTP option.

Chip Enable (CE)

A logic-high on CE pin puts the MAX77826 into standby mode (enabled). In standby mode, all user registers are accessible through I²C so that the host processor can

overwrite the default output voltages of regulators and each regulator can be enabled by either I²C or the GPIO input if applicable.

When the CE pin goes high, the MAX77826 turns on the top-level bias circuitry, and it takes typically 85 μs to settle. As soon as the top-level bias is ready, BUCK BOOST is ready to be turned on. However, BUCK and LDOs require additional 85 μs (typ) for REFBYP to settle. Total, it takes 170 μs (85 μs + 85 μs) for REFBYP to settle from CE = high. In the worst-case scenario, it can take up to 230 μs . Once REFBYP is ready, all the regulators are allowed to be tuned on through I²C or the ENx pins. In case the regulators are enabled before the bias circuitry is ready, the regulators require longer time to startup.

When CE pin is pulled low, the MAX77826 goes into shutdown mode (disabled) and turns off all the regulators regardless of ENx pins. This event also resets all Type-O registers to their POR default values.

Immediate Shutdown Events

The following events initiate immediate shutdown: thermal protection ($T_{\text{J}} > +165^{\circ}\text{C}$), $V_{\text{SYS}} < V_{\text{SYS}} \text{ UVLO}$ falling threshold ($V_{\text{UVLO_F}}$), $V_{\text{IO}} < V_{\text{IO}} \text{ OK}$ threshold ($V_{\text{TH_VIO_OK}}$)

The events in this category are associated with potentially hazardous system states. Powering down the host processor and resetting all Type-O registers help mitigate any issues that can occur due to these potentially hazardous conditions. Note that the MAX77826 cannot be enabled until the junction temperature drops below $+150^{\circ}\text{C}$ in case thermal protection caused the immediate shutdown.

Operating Mode (OPMD)

Each regulator (BUCK, BUCK BOOST, and LDO) has independent register bits to control its operating mode. These bits determines on/off operation during initial startup, output enable control, and sleep mode operation based on the enable control logic of each regulator. The POR default values of output enable bits (x_{EN}) are 0 (output off).

Enable Control Logic1

BUCK, BUCK BOOST, and LDO12 have independent I²C enable bits and dedicated GPIO enable pins (ENB, ENBB, and ENL12). As shown in Table 1, regulators can be turned on/off by ENx or I²C control bits.

Enable Control Logic 2

LDO1–LDO11 and LDO13–LDO15 have independent I²C enable bits. As shown in Table 2, regulators can be turned on/off by the I²C control bits.

Reset Conditions

System Reset

When V_{SYS} voltage drops below its POR threshold (≈1.55V), all Type-S1 registers are reset to their POR default values.

Off Reset

Off reset occurs by any power-off events. This condition resets all Type-O registers to their POR default values.

Table 1. Enable Control Logic 1 Truth Table

CE	ENx	B_EN BB_EN L12_EN	B_LPM L12_LPM	OPERATING MODE
Low	x	x	x	Device off
High	Low	0	x	Output off
High	High	x	1	Output on (low power mode*)
High	High	x	0	Output on
High	x	1	1	Output on (low power mode*)
High	x	1	0	Output on

*The BUCK BOOST regulator does not have a low power mode.

Table 2. Enable Control Logic 2 Truth Table

Low	x	x	Device off
High	0	x	Output off
High	1	1	Output on (low power mode)
High	1	0	Output on

Interrupt and Mask

IRQB pin is used to indicate to the host processor that the status on the MAX77826 has changed. IRQB signal is asserted whenever one or more interrupts are triggered. The host processor reads the interrupt source register (ADDR 0x00) and the interrupt registers as indicated by the interrupt source register in order to see the cause of interrupt event.

Each interrupt register can be read at a time. IRQB pin goes high (cleared) as soon as the read sequence finishes. If an interrupt is captured during the read sequence, IRQB pin is held low. Note that the interrupt source register is cleared when the corresponding interrupt registers are read by the host processor.

Each interrupt can be masked (disabled) by setting the corresponding interrupt mask register bit. In case an interrupt mask bit is set (masked), the corresponding interrupt bit is not supposed to be set even when the interrupt condition is met. As a result, the IRQB pin stays high for this event. If the mask bit is cleared for an active interrupt, the corresponding interrupt bit is set to pull the IRQB pin low.

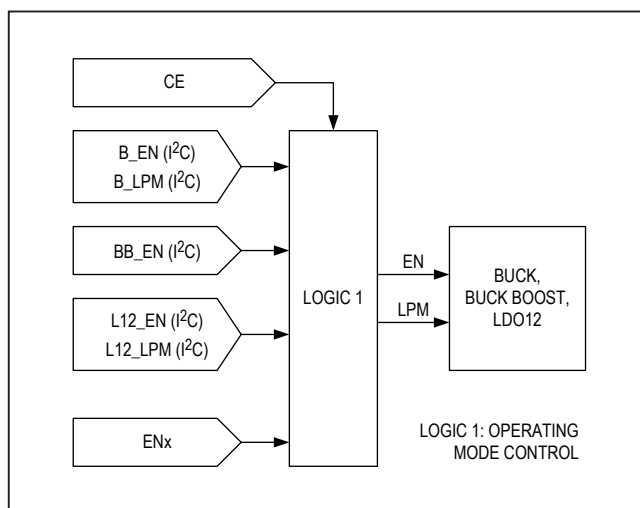

Figure 1. Enable Control Logic 1

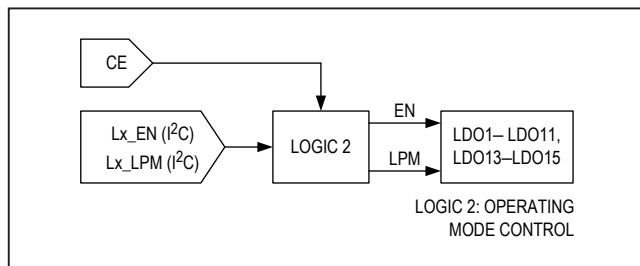

Figure 2. Enable Control Logic 2

BUCK Regulator

The MAX77826 includes a 3A current-mode BUCK regulator. In normal operation, BUCK consumes only 22 μ A quiescent current. In low power mode, the quiescent current is decreased to 8 μ A with reduced load capability.

The summary of features is:

- 3A of maximum output current rating
- 2.6V to 5.5V input voltage range
- Output voltage range from 0.50V to 1.80V in 6.25mV steps
- $\pm 1\%$ (typ) output voltage DC accuracy
- 2MHz (typ) switching frequency
- Automatic SKIP/PWM or forced PWM modes
- > 90% peak efficiency
- Programmable slew rate for increasing output voltage settings

Operating Mode Control

The operating mode bit resides in the top level that controls the enable/disable state of BUCK through the B_EN register and also controls the operating mode (low power or normal mode) through the B_LPM register.

SKIP/Forced PWM Operation

In normal operating mode, BUCK automatically transitions from SKIP mode to fixed frequency operation as load current increases. For operating modes where lowest output ripple is required, forced PWM switching behavior can be enabled by writing 1 to B_FPWM bit.

Low Power Mode Operation

In low power mode, the quiescent current is reduced from 22 μ A to 8 μ A. The output current is limited to 10mA. It is not recommended to adjust the output voltage in low power mode. The regulator does not automatically enter/exit low power mode. The host processor needs to control low power mode operation in times of known low power states through the I²C serial interface.

Startup and Soft-Start

When starting up BUCK regulator, the bias circuitry must be enabled and provided with adequate time to settle. The bias circuitry is guaranteed to settle within 250 μ s, at which time, the BUCK regulators' power-up sequences can commence. Note that attempting to implement a power-up sequence before BIASOK signal is generated results in all enabled regulators starting up at the same time.

The BUCK regulator supports starting into a prebiased output. For example, if the output capacitor has an initial voltage of 0.4V when the regulator is enabled, the regulator gradually increases the capacitor voltage to the required target voltage such as 1.0V. This is unlike other regulators without the start into prebias feature in which they can force the output capacitor voltage to 0V before the soft-start ramp begins.

The BUCK regulator has a soft-start rate of 14mV/ μ s. The controlled soft-start rate and BUCK regulator current limit (I_{LIMP}) limit the input inrush current to the output capacitor (I_{INRUSH}). $I_{INRUSH} = \min(I_{LIMP} \text{ and } C_{OUT} \times dv/dt)$. Note that the input current of BUCK regulator is lower than the inrush current to the output capacitor by the ratio of output to input voltage.

Output Voltage Setting

The output voltage is programmable from 0.50V to 1.80V in 6.25mV steps to allow fine adjustment to the processor supply voltage under light load conditions to minimize power loss within the processor. The default output voltage is set by an OTP option at the factory. The default output voltage can be overwritten by changing the contents in B_VOUT[7:0] register prior to enabling the regulator. The output voltage can also be adjusted during normal operation.

Changing Output Voltage While Operating

In a typical smartphone or tablet application, there are several power domains in which the operating frequency of the processor increases or decreases (DVFS). When the operating frequency needs to be changed, it is expected that BUCK regulator responds to a command to change the output voltages to new target values quickly. The high peak current limit, coupled with low inductance and small output capacitance, allows the BUCK regulator to respond to a positive step change in output voltage and settle to the new target value quickly. The BUCK regulator provides programmable ramp-up slew rates to accommodate different requirements.

For a negative step change in output voltage, the settling time is not critical. In forced PWM mode (either B_FPWM bit or B_FSRAD bit is enabled), the negative inductor current through NMOS discharges energy from the output capacitor to help the output voltage decrease to the new target value faster. In skip mode, negative inductor current is not allowed so that the output voltage settling time is dependent on the load current and the output capacitance.

Output Voltage Slew Rate Control

The BUCK regulator supports programmable slew rate control feature when increasing and decreasing the output voltage. The ramp-up slew rate can be set to 12.5mV/μs, 25mV/μs, 50mV/μs or 100mV/μs independently through the B_RAMP[1:0] bits, while the ramp-down slew rate is fixed to 6.25mV/μs.

Output Active Discharge Resistance

BUCK provides an internal 100Ω resistor for output active discharge function. If the active discharge function is enabled (B_AD = 1), the internal resistor discharges the energy stored in the output capacitor to GND whenever the regulator is disabled.

Either the regulator remains enabled or the active discharge function is disabled (B_AD = 0), the internal resistor is disconnected from the output. If the active discharge function is disabled, the output voltage decays at a rate that is determined by the output capacitance and the load current when the regulator is turned off.

Inductor Selection

BUCK is optimized for a 0.47μH inductor. The lower the inductor DCR, the higher BUCK efficiency is. Users need to trade off inductor size with DCR value and choose a suitable inductor for BUCK.

Input Capacitor Selection

The input capacitor, C_{IN}, reduces the current peaks drawn from the battery or input power source and reduces switching noise in the IC. The impedance of C_{IN} at the switching frequency should be kept very low. Ceramic capacitors with X5R or X7R dielectrics are highly recommended

due to their small size, low ESR, and small temperature coefficients. For most applications, a 10μF capacitor is sufficient.

Output Capacitor Selection

The output capacitor, C_{OUT}, is required to keep the output voltage ripple small and to ensure regulation loop stability. C_{OUT} must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. Due to the unique feedback network, the output capacitance can be very low. The recommended minimum output capacitance for BUCK is 22μF.

BUCK BOOST Regulator

The MAX77826 BUCK BOOST regulator utilizes a four-switch H-bridge configuration to realize BUCK, BUCK BOOST, and BOOST operating modes. In this way, this topology maintains output voltage regulation when the input voltage is greater than, equal to, or less than the output voltage. The MAX77826 BUCK BOOST is ideal in Li-ion battery powered applications, providing 2.6V to 4.1875V output voltage and up to 2A output current across the input voltage range. High switching frequency and a unique control algorithm allow the smallest solution size, low output noise, and highest efficiency across a wide input voltage and output current range.

The MAX77826 BUCK BOOST regulator typically generates a 3.50V output voltage. The input current limit is set to 3.5A (typ) to guarantee delivery of 2A at 3.50V from 3.0V input. Internal soft-start limits the inrush current at startup.

Table 3. Suggested Inductors for BUCK

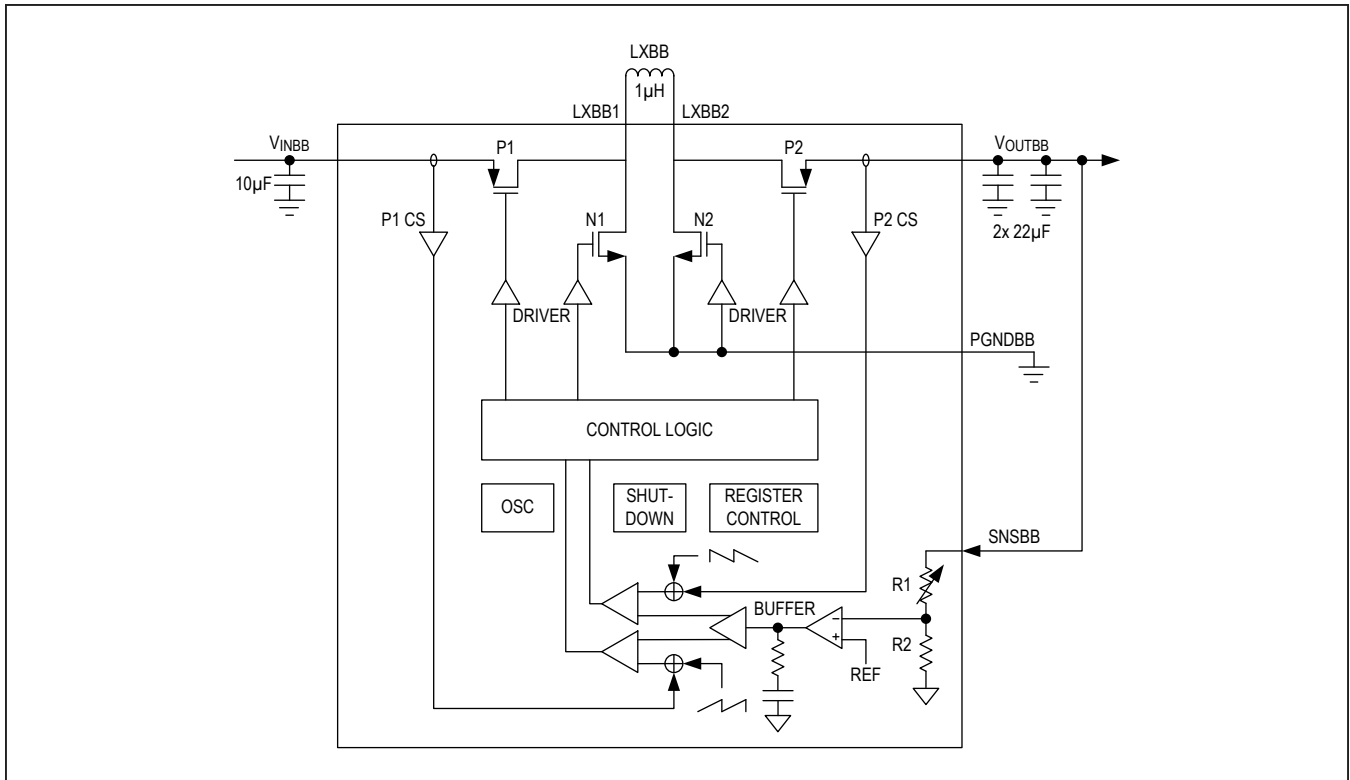

Figure 3. BUCK BOOST Block Diagram

H-Bridge Controller

The H-bridge architecture operates at 3MHz fixed frequency with a pulse width modulated (PWM), current mode control scheme. This topology is in a cascade of a BOOST regulator and a BUCK regulator using a single inductor and output capacitor. BUCK, BUCK BOOST, and BOOST stages are 100% synchronous for highest efficiency in portable applications.

There are three phases implemented with the H-bridge switch topology, as shown in Figure 4:

Φ1 switch period (Phase 1: P1 = on, N2 = on) stores energy in the inductor, ramping up the inductor current at a rate proportional to the input voltage divided by inductance; V_{INBB}/L .

Φ2 switch period (Phase 2: P1 = on, N3 = on) ramps the inductor current up or down, depending on the differential voltage across the inductor, divided by inductance; $\pm(V_{INBB} - V_{OUTBB})/L$.

Φ3 switch period (Phase 3: N1 = on, N3 = on) ramps down the inductor current at a rate proportional to the output voltage divided by inductance, $-V_{OUTBB}/L$.

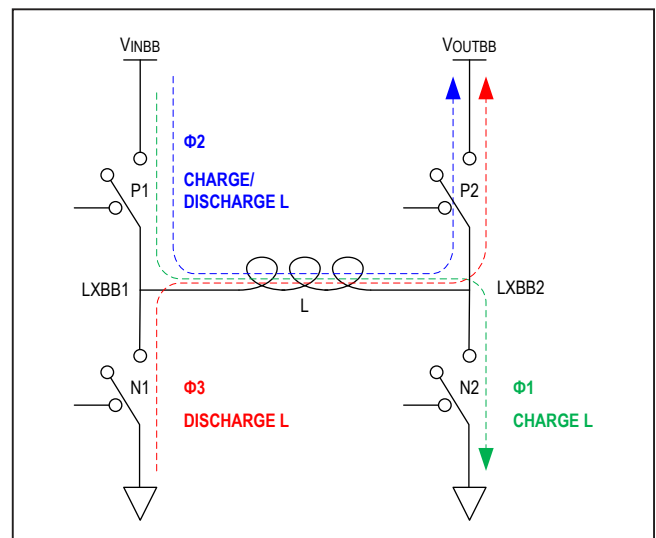

Figure 4. BUCK BOOST Switching Intervals

2-Phase BUCK topology is utilized when $V_{INBB} > V_{OUTBB}$. A switching cycle is completed in one clock periods. Switch period $\Phi 2$ is followed by switch period $\Phi 3$, resulting in an inductor current waveform similar to [Figure 5](#).

3-Phase BUCK topology is utilized when $V_{INBB} > V_{OUTBB}$ and 2-Phase BUCK cannot support V_O . Switch period is: $\Phi 1 \rightarrow \Phi 2 \rightarrow \Phi 3$. Switch period $\Phi 1$ is fixed. This results in an inductor current waveform similar to [Figure 6](#).

2-Phase BOOST topology is utilized when $V_{INBB} < V_{OUTBB}$. A switching cycle is completed in one clock periods. Switch period $\Phi 1$ is followed by switch period $\Phi 2$, resulting in an inductor current waveform similar to [Figure 7](#).

3-Phase BOOST topology is utilized when $V_{INBB} < V_{OUTBB}$ and 2-Phase BOOST cannot support V_O . Switch period is: $\Phi 1 \rightarrow \Phi 2 \rightarrow \Phi 3$. Switch period $\Phi 3$ is fixed. This results in an inductor current waveform similar to [Figure 8](#).

Inductor Selection

BUCK BOOST is optimized for a $1\mu\text{H}$ inductor. The lower the inductor DCR, the higher BUCK BOOST efficiency is.

Users need to trade off inductor size with DCR value and choose a suitable inductor for BUCK BOOST.

The input capacitor, C_{IN} , reduces the current peaks drawn from the battery or input power source and reduces switching noise in the IC. The impedance of C_{IN} at the switching frequency should be kept very low. Ceramic capacitors with X5R or X7R dielectrics are highly recommended due to their small size, low ESR, and small temperature coefficients. For most applications, a $10\mu\text{F}$ capacitor is sufficient.

Output Capacitor Selection

The output capacitor, C_{OUT} , is required to keep the output voltage ripple small and to ensure regulation loop stability. C_{OUT} must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. Due to the unique feedback network, the output capacitance can be very low. The recommended minimum output capacitance for BUCK BOOST is $47\mu\text{F}$.

Linear Regulators

The MAX77826 provides 15 low dropout linear regulators including 3 NMOS LDOs, 6 PMOSLV LDOs, and 6 PMOSLS LDOs. Each of these regulators draws 27 μ A/18 μ A (NMOS/PMOS) of quiescent current in normal operating mode and < 5 μ A in low power mode. PMOSLV LDOs allow input voltages as low as 1.7V for optimized system efficiency.

All regulators can be operated in low power mode that supports up to 5mA of maximum load current.

The summary of features is:

- 3 NMOS LDOs (V_{OUT} range: 0.6V to 2.1875V with 12.5mV step)
 - 1 x 150mA
 - 1 x 450mA
 - 1 x 600mA
- 6 PMOSLV LDOs (V_{OUT} range: 0.8V to 3.975V with 25mV step)
 - 3 x 150mA
 - 3 x 300mA
- 6 PMOSLS LDOs (V_{OUT} range: 0.8V to 3.975V with 25mV step)
 - 3 x 150mA
 - 3 x 300mA
 - $\pm 1.5\%$ typical Output Voltage DC Accuracy
 - 70dB PSRR at 1kHz

LDO Reference

The MAX77826 has a single LDOREF bias rail. LDOREF is enabled or disabled along with the central bias block (SBIA) so that LDOREF is ready whenever any LDO turns on. It has a very low quiescent current of 2 μ A typical.

Operating Mode Control

The operation mode bits for each LDO reside in the top level that controls the enable/disable state for each LDO through the Lx_EN signal and also controls the operation modes (low power or normal mode) for each LDO through the Lx_LPM signal.

Low Power Mode

In low power mode, the quiescent current of each LDO is reduced from 27 μ A/18 μ A (NMOS/PMOS) to less than 5 μ A. The output current of each LDO is limited to 5mA if operating in low power mode. Each LDO can be individually enabled to operate in low power mode.

Soft-Start and Dynamic Voltage Change

When a regulator is enabled, the output voltage ramps to the final voltage at the slew rate of 30mV/ μ s. The 30mV/ μ s ramp rate results in around 30mA inrush current with a 1.0 μ F output capacitor under no load condition. For a 1.8V LDO ramping from 0V, the output voltage regulation is achieved within 60 μ s. The soft-start ramp rate is also the rate of change at the output when switching dynamically between two output voltages without disabling. The soft-start circuitry of LDOs supports starting into a pre-biased output.

Output Active Discharge

Each LDO provides an internal 100 Ω resistor for output active discharge function. If the active discharge function is enabled (Lx_AD = 1), the internal resistor discharges the energy stored in the output capacitor to GND whenever the regulator is disabled.

Either the regulator remains enabled or the active discharge function is disabled (Lx_AD = 0), the internal resistor is disconnected from the output. If the active discharge function is disabled, the output voltage decays at a rate that is determined by the output capacitance and the load current when the regulator is turned off.

Thermal Considerations

In most applications, the MAX77826 does not dissipate much heat because of its high efficiency. However, in applications where the MAX77826 runs with heavy loads at high ambient temperature, the junction temperature can exceed the maximum operating temperature. In case the junction temperature reaches approximately +165 $^{\circ}$ C, the thermal overload protection triggers. The maximum power dissipation of the MAX77826 depends on the thermal resistance of the IC package and PCB. The power dissipated in the device is:

$$P_D = P_{OUT} \times (1/\eta - 1)$$

where η is the efficiency of the regulator and P_{OUT} is the output power delivered to the load.

The maximum allowed power dissipation is:

$$P_{MAX} = (T_{JMAX} - T_A)/\theta_{JA}$$

$T_{JMAX} - T_A$ is the temperature difference between the maximum rated junction temperature and the ambient temperature, θ_{JA} is the thermal resistance between the junction and the ambient.

Serial Interface

The I²C-compatible, 2-wire serial interface is used for regulator on/off control, setting output voltages, and other functions. See the Register Map for details.

The I²C serial bus consists of a bidirectional serial-data line (SDA) and a serial clock (SCL). I²C is an open-drain bus. SDA and SCL require pullup resistors (500Ω or greater). Optional 24Ω resistors in series with SDA and SCL help to protect the device inputs from high voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus lines.

System Configuration

I²C bus is a multimaster bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.

The figure above shows an example of a typical I²C system. A device on I²C bus that sends data to the bus is called a transmitter. A device that receives data from the bus is called a receiver. The device that initiates a data transfer and generates SCL clock signals to control the data transfer is a master. Any device that is addressed by the master is considered a slave. When the MAX77826 I²C-compatible interface is operating in normal mode, it is a slave on I²C bus, and it can be both a transmitter and a receiver.

Bit Transfer

One data bit transfers for each SCL clock cycle. The data on SDA must remain stable during the high portion of SCL clock pulse. Changes in SDA while SCL is high are control signals (START and STOP conditions).

START and STOP Conditions

When the I²C serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP condition is a low-to-high transition on SDA, while SCL is high.

A START condition from the master signals the beginning of a transmission to the MAX77826. The master terminates transmission by issuing a NOT ACKNOWLEDGE followed by a STOP condition.

A STOP condition frees the bus. To issue a series of commands to the slave, the master can issue REPEATED START (Sr) commands instead of a STOP command to maintain control of the bus. In general, a REPEATED START command is functionally equivalent to a regular START command.

When a STOP condition or incorrect address is detected, the MAX77826 internally disconnects SCL from the I²C serial interface until the next START condition, minimizing digital noise and feedthrough.

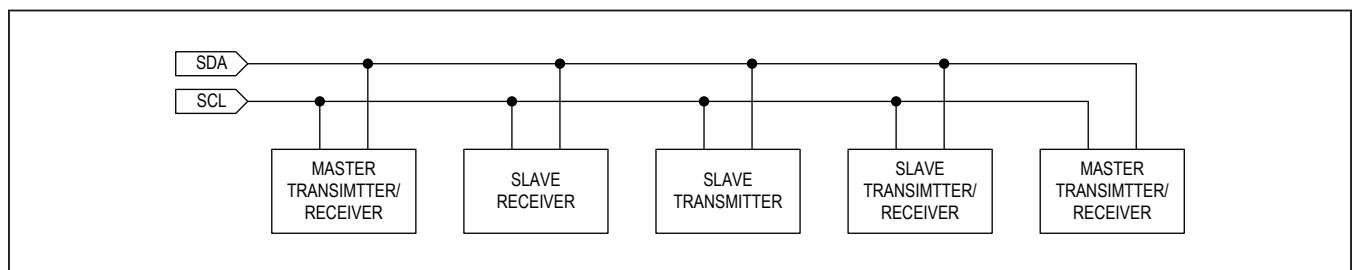

Figure 9. Functional Logic Diagram for Communications Controller

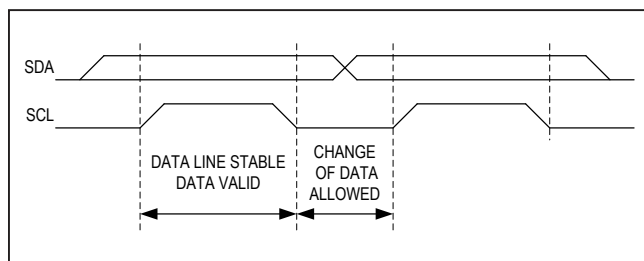

Figure 10. I²C Bit Transfer

Figure 11. START and STOP Conditions

Acknowledge

Both the I²C bus master and MAX77826 (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each 9-bit data packet. To generate an ACKNOWLEDGE (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse. To generate a NOT-ACKNOWLEDGE (nA), the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

Slave Address

The I²C slave address of the MAX77826 is shown in Table 5.

In general, the clock signal generation for the I²C bus is the responsibility of the master device. The I²C specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The MAX77826 does not use any form of clock stretching to hold down the clock line.

General Call Address

The MAX77826 does not implement I²C specification general call address. If the MAX77826 sees the general call address (0000000b), it does not issue an ACKNOWLEDGE (A).

Table 5. Power Management Slave Address

SLAVE ADDRESS (7 bit)	SLAVE ADDRESS (Write)	SLAVE ADDRESS (Read)
110 0000	0xC0 (1100 0000)	0xC1 (1100 0001)

Figure 12. Slave Address Byte Example for Power Block

Communication Speed

The MAX77826 provides an I²C 3.0-compatible (3.4MHz) serial interface.

- I²C revision 3-compatible serial communications channel
 - 0Hz to 100kHz (standard mode)
 - 0Hz to 400kHz (fast mode)
 - 0Hz to 1MHz (fast mode plus)
 - 0Hz to 3.4MHz (high-speed mode)
 - Does not utilize I²C clock stretching

Operating in standard mode, fast mode and fast mode plus do not require any special protocols. The main consideration when changing the bus speed through this range is the combination of the bus capacitance and pullup resistors. Higher time constants created by the bus capacitance and pullup resistance (C x R) slow the bus operation. Therefore, when increasing bus speeds the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the *Pullup Resistor Sizing* section of I²C revision 3.0 specification for detailed guidance on the pullup resistor selection. In general for bus capacitances of 200pF, a 100kHz bus needs 5.6kΩ pullup resistors, a 400kHz bus needs about a 1.5kΩ pullup resistors, and a 1MHz bus needs 680Ω pullup resistors. Note that the pullup resistor dissipates power when the open-drain bus is low. The lower the value of the pullup resistor, the higher the power dissipation is (V²/R).

Operating in high-speed mode requires some special considerations. For the full list of considerations, refer to the I²C 3.0 specification. The major considerations with respect to the MAX77826 are:

- The I²C bus master uses current source pullups to shorten the signal rise times.
- The I²C slave must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus speed.
- The communication protocols need to utilize the high-speed master code.

At power-up and after each STOP condition, the MAX77826 inputs filters are set for standard mode, fast mode, or fast mode plus (i.e., 0Hz to 1MHz). To switch the input filters for high-speed mode, use the high-speed master code protocols that are described in [Communication Protocols](#) section.

Communication Protocols

The MAX77826 supports both writing and reading from its registers. Table TBD shows the I2C communication protocols for each functional block. The power block uses the same communications protocols.

Writing to a Single Register

Figure 13 shows the protocol for the I2C master device to write one byte of data to the MAX77826. This protocol is the same as the SMBus specification's write byte protocol. The write byte protocol is as follows:

- 1) The master sends a START command (S).
- 2) The master sends the 7-bit slave address followed by a write bit ($R/\bar{W} = 0$).
- 3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4) The master sends an 8-bit register pointer.

- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave updates with the new data
- 8) The slave acknowledges or does not acknowledge the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
- 9) The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

Writing to Sequential Registers

Figure 14 shows the protocol for writing to a sequential registers. This protocol is similar to the write byte protocol, except the master continues to write after it receives the first byte of data. When the master is done writing, it issues a STOP or REPEATED START. The writing to sequential registers protocol is as follows:

- 1) The master sends a START command (S).
- 2) The master sends the 7-bit slave address followed by a write bit ($R/\bar{W} = 0$).

Figure 13. Writing to a Single Register with Write Byte Protocol

- 3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA LOW.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register, and the data becomes active.
- 8) Steps 6 and 7 are repeated as many times as the master requires.
- 9) During the last acknowledge related clock pulse, the master can issue an ACKNOWLEDGE (A) or a NOT ACKNOWLEDGE (nA).
- 10) The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

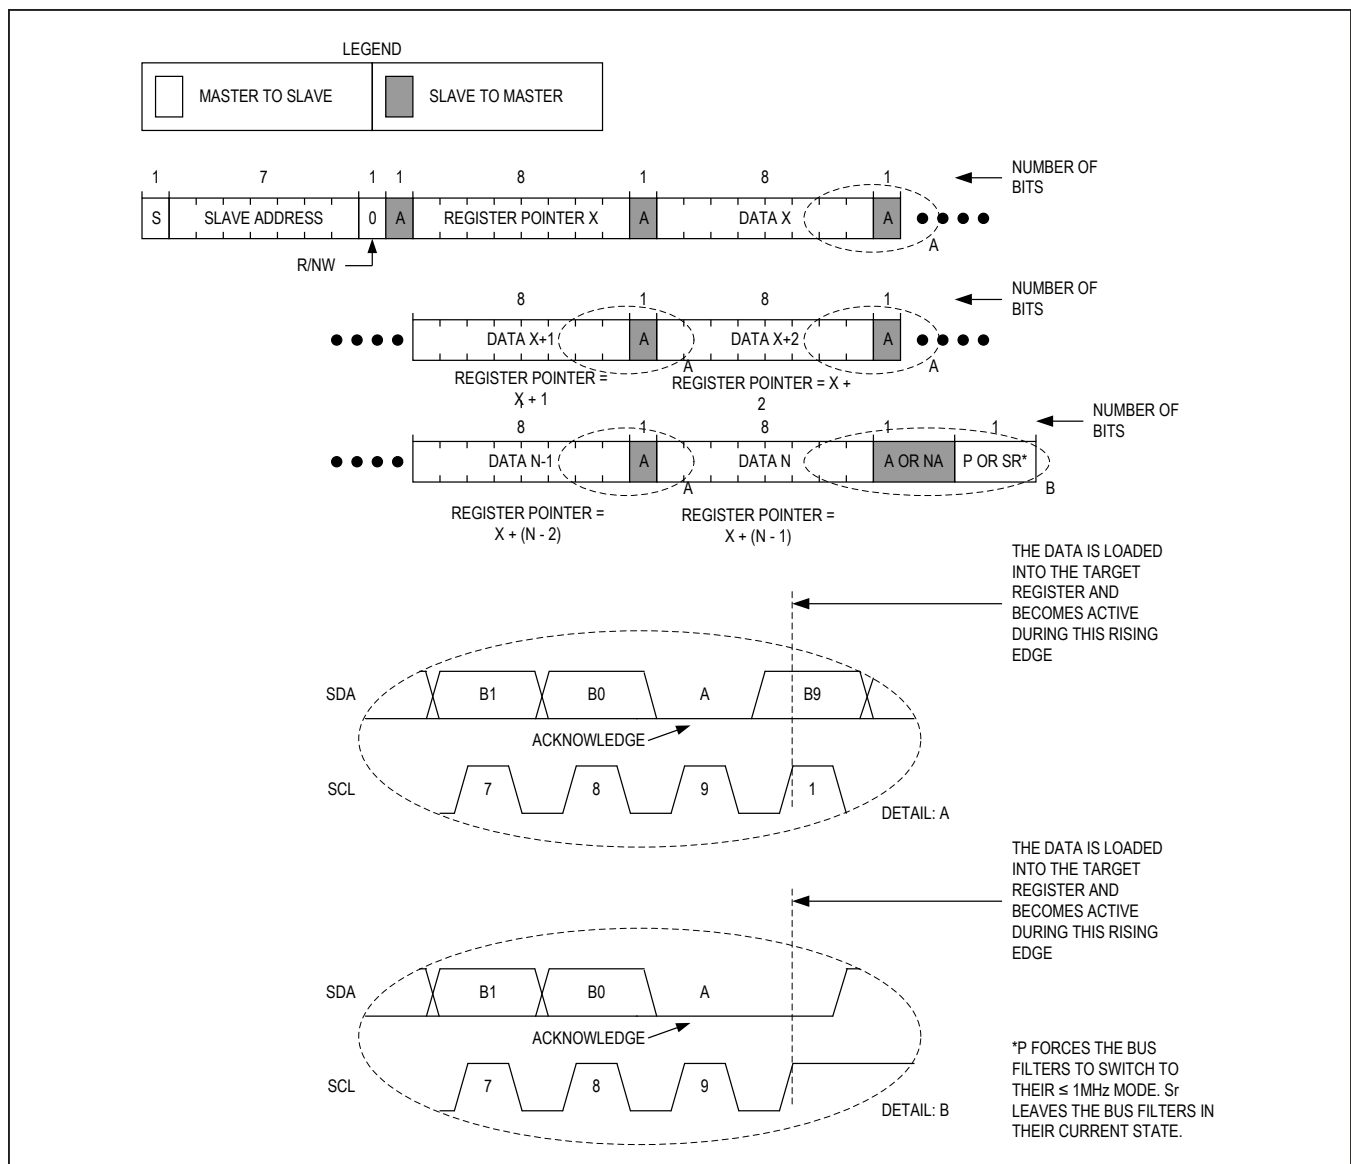

Figure 14. Writing to Sequential Registers X to N

Writing Multiple Bytes using Register-Data Pairs

Figure 15 shows the protocol for I²C master device to write multiple bytes to the MAX77826 using register-data pairs. This protocol allows I²C master device to address the slave only once and then send data to multiple registers in a random order. Registers can be written continuously until the master issues a STOP condition. The multiple byte register-data pair protocol is as follows:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit.
- 3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
- 8) Steps 4 to 7 are repeated as many times as the master requires.
- 9) The master sends a STOP condition. During the rising edge of the stop related SDA edge, the data byte that was previously written is loaded into the target register and becomes active.

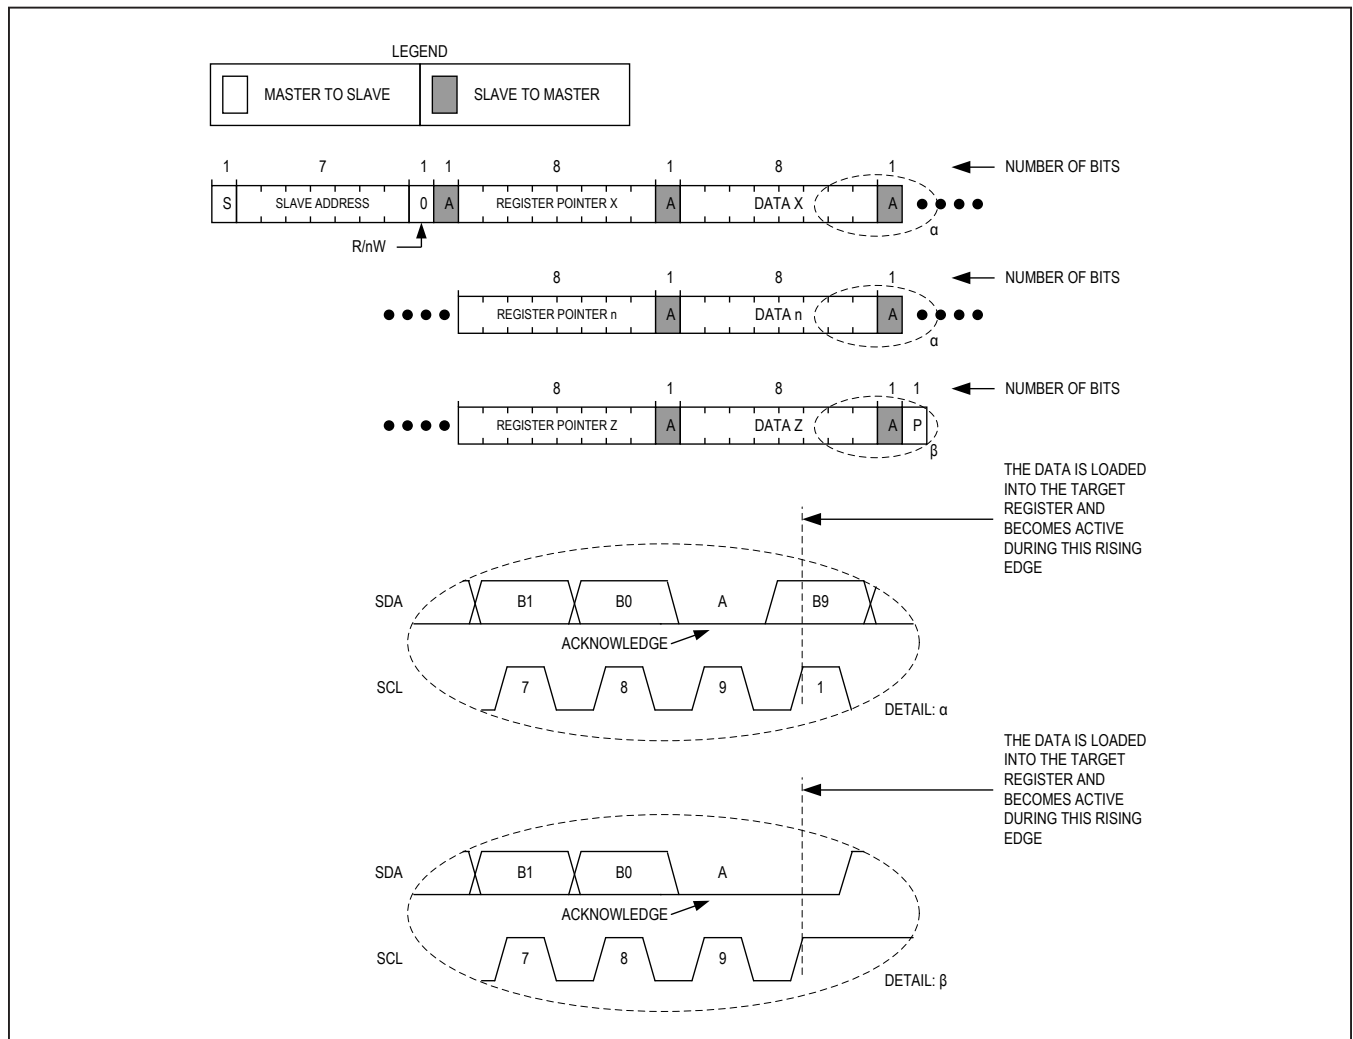

Figure 15. Writing to Multiple Registers with Multiple Byte Register-Data Pairs Protocol

Reading from a Single Register

The I²C master device reads one byte of data to the MAX77826. This protocol is the same as SMBus specification's read byte protocol. The read byte protocol is as follows:

- 1) The master sends a START command (S).
- 2) The master sends the 7-bit slave address followed by a write bit ($R/\overline{W} = 0$).
- 3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a REPEATED START command (Sr).
- 7) The master sends the 7-bit slave address followed by a read bit ($R/\overline{W} = 1$).
- 8) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9) The addressed slave places 8 bit of data on the bus from the location specified by the register pointer.
- 10) The master issues a NOT ACKNOWLEDGE (nA).
- 11) The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a P ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a REPEATED START command (Sr).
- 7) The master sends the 7-bit slave address followed by a read bit ($R/\overline{W} = 1$).
- 8) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9) The addressed slave places 8 bit of data on the bus from the location specified by the register pointer.
- 10) The master issues an ACKNOWLEDGE (A) signaling the slave that it wishes to receive more data.
- 11) Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT ACKNOWLEDGE (nA) to signal that it wishes to stop receiving data.
- 12) The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

Note that every time MAX77826 receives a STOP, its register pointer is set to 0x00. If reading register 0x00 after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

Reading from Sequential Registers

Figure 16 shows the protocol for reading from sequential registers. This protocol is similar to the read byte protocol except the master issues an ACKNOWLEDGE (A) to signal the slave that it wants more data. When the master has all the data it requires, it issues a NOT ACKNOWLEDGE (nA) and a STOP (P) to end the transmission. The continuous read from sequential registers protocol is as follows:

- 1) The master sends a START command (S).
- 2) The master sends the 7-bit slave address followed by a write bit ($R/\overline{W} = 0$).
- 3) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA LOW.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a REPEATED START command (Sr).
- 7) The master sends the 7-bit slave address followed by a read bit ($R/\overline{W} = 1$).
- 8) The addressed slave asserts an ACKNOWLEDGE (A) by pulling SDA low.
- 9) The addressed slave places 8 bit of data on the bus from the location specified by the register pointer.
- 10) The master issues an ACKNOWLEDGE (A) signaling the slave that it wishes to receive more data.
- 11) Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT ACKNOWLEDGE (nA) to signal that it wishes to stop receiving data.
- 12) The master sends a STOP condition (P) or a REPEATED START condition (Sr). Issuing a STOP (P) ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START (Sr) leaves the bus input filters in their current state.

Note that every time the MAX77826 receives a STOP its register pointer is set to 0x00. If reading register 0x00 after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

Engaging HS-Mode for Operation up to 3.4MHz

Figure 17 shows the protocol for engaging HS mode operation. HS mode operation allows for a bus operating speed up to 3.4MHz. The engaging HS mode protocol is as follows:

- 1) Begin the protocol while operating at a bus speed of 1MHz or lower.
- 2) The master sends a START command (S).
- 3) The master sends the 8-bit master code of 00001xxx_b where xxx_b are don't care bits.
- 4) The addressed slave issues a NOT ACKNOWLEDGE (nA).
- 5) The master may now increase its bus speed up to 3.4MHz and issue any read/write operation.
- 6) The master may continue to issue high-speed read/write operations until a STOP (P) is issued. Issuing a STOP (P) ensures that the bus input filters are set for 1MHz or slower operation. After a STOP has been issued, steps 1 to 6 in the above algorithm may be skipped.

7:6	B_RAMP[1:0]	00	Rising Ramp Rate Control 00b: 12.5mV/μs 01b: 25mV/μs 10b: 50mV/μs 11b: 100mV/μs	
5:4	RSVD	00		
3	B_AD	1	Output Active Discharge 0: Disable 1: Enable	
2	B_FPWM	0	Forced PWM 0: Turn off Forced PWM (Automatic SKIP mode operation under light load) 1: Turn on Forced PWM Mode	
1	RSVD	0		
0	B_FSRAD	1	Falling Slew Rate Active Discharge 0: Disable Active Discharge BUCK is allowed to operate in SKIP mode during the time the output voltage decreases (only if B3_FPWM = 0). In SKIP mode, BUCK cannot sink current from the output capacitor and the output voltage falling slew rate is a function of the external load. If the load is heavy, the output voltage falling slew rate is limited to 6.25mV/μs. If the load is light, the output voltage falling slew rate is a function of the output capacitance and the load. Note that the internal feedback string always imposes a 2μA load on the output. 1: Enable Active Discharge BUCK operates in forced PWM mode during the time the output voltage decreases. In forced PWM mode, BUCK can sink current from the output capacitor to ensure that the output voltage falls at the rate of 6.25mV/μs. To ensure a smooth output voltage ramp-down, forced PMW mode remains engaged for 50μs after the output voltage decreases to its target voltage _e .
