

Low Voltage 1:27 Clock Distribution Chip

The MPC941 is a 1:27 low voltage clock distribution chip. The device features the capability to select either a differential LVPECL or an LVCMOS compatible input. The 27 outputs are LVCMOS compatible and feature the drive strength to drive 50Ω series or parallel terminated transmission lines. With output-to-output skews of 250ps, the MPC941 is ideal as a clock distribution chip for the most demanding of synchronous systems. For a similar product with a smaller number of outputs, please consult the MPC940 data sheet.

- LVPECL or LVCMOS Clock Input
- 250ps Maximum Output-to-Output Skew
- Drives Up to 54 Independent Clock Lines
- Maximum Output Frequency of 250MHz
- High Impedance Output Enable
- 48-Lead LQFP Packaging
- 3.3V or 2.5V V_{CC} Supply Voltage

With a low output impedance, in both the HIGH and LOW logic states, the output buffers of the MPC941 are ideal for driving series terminated transmission lines. More specifically, each of the 27 MPC941 outputs can drive two series terminated 50Ω transmission lines. With this capability, the MPC941 has an effective fanout of 1:54. With this level of fanout, the MPC941 provides enough copies of low skew clocks for most high performance synchronous systems.

The differential LVPECL inputs of the MPC941 allow the device to interface directly with an LVPECL fanout buffer like the MC100EP111 to build very wide clock fanout trees or to couple to a high frequency clock source. The LVCMOS input provides a more standard interface for applications requiring only a single clock distribution chip at relatively low frequencies. In addition, the two clock sources can be used as a test clock interface as well as the primary system clock. A logic HIGH on the LVCMOS_CLK_Sel pin will select the LVCMOS level clock input.

The MPC941 is fully 3.3V and 2.5V compatible. The 48-lead LQFP package was chosen to optimize performance, board space and cost of the device. The 48-lead LQFP has a 7x7mm body size.

- a. AC characteristics apply for parallel output termination of 50Ω to V_{TT} .
 b. AC characteristics are guaranteed up to f_{max} . Please refer to the applications section for information on power consumption versus operating frequency and thermal management.
 c. Fast input signal transition times are required to maintain part-to-part skew specification. If part-to-part skew is not critical to the application, signal transition times smaller than 3 ns can be applied to the MPC941.

APPLICATIONS INFORMATION

Driving Transmission Lines

The MPC941 clock driver was designed to drive high speed signals in a terminated transmission line environment. To provide the optimum flexibility to the user the output drivers were designed to exhibit the lowest impedance possible. With an output impedance of less than 20Ω the drivers can drive either parallel or series terminated transmission lines. For more information on transmission lines the reader is referred to application note AN1091 in the Timing Solutions data book (DL207/D).

In most high performance clock networks point-to-point distribution of signals is the method of choice. In a point-to-point scheme either series terminated or parallel terminated transmission lines can be used. The parallel technique terminates the signal at the end of the line with a 50Ω resistance to VCC/2. This technique draws a fairly high level of DC current and thus only a single terminated line can be driven by each output of the MPC941 clock driver. For the series terminated case however there is no DC current draw, thus the outputs can drive multiple series terminated lines. Figure 1 “Single versus Dual Transmission Lines” illustrates an output driving a single series terminated line vs two series terminated lines in parallel. When taken to its extreme the fanout of the MPC941 clock driver is effectively doubled due to its capability to drive multiple lines.

Figure 1. Single versus Dual Transmission Lines

The waveform plots of Figure 2 “Single versus Dual Waveforms” show the simulation results of an output driving a single line vs two lines. In both cases the drive capability of the MPC941 output buffer is more than sufficient to drive 50Ω transmission lines on the incident edge. Note from the delay measurements in the simulations a delta of only 43ps exists between the two differently loaded outputs. This suggests that the dual line driving need not be used exclusively to maintain the tight output-to-output skew of the MPC941. The output waveform in Figure 2 shows a step in the waveform, this step is caused by the impedance mismatch seen looking into the driver. The parallel combination of the 36Ω series resistor plus the output impedance does not

match the parallel combination of the line impedances. The voltage wave launched down the two lines will equal:

$$V_L = V_S (Z_o / (R_s + R_o + Z_o))$$

$$Z_o = 50\Omega \parallel 50\Omega$$

$$R_s = 36\Omega \parallel 36\Omega$$

$$R_o = 14\Omega$$

$$V_L = 3.0 (25 / (18 + 14 + 25)) = 3.0 (25 / 57)$$

$$= 1.31V$$

At the load end the voltage will double, due to the near unity reflection coefficient, to 2.5V. It will then increment towards the quiescent 3.0V in steps separated by one round trip delay (in this case 4.0ns).

Figure 2. Single versus Dual Waveforms

Since this step is well above the threshold region it will not cause any false clock triggering, however designers may be uncomfortable with unwanted reflections on the line. To better match the impedances when driving multiple lines the situation in Figure 3 “Optimized Dual Line Termination” should be used. In this case the series terminating resistors are reduced such that when the parallel combination is added to the output buffer impedance the line impedance is perfectly matched.

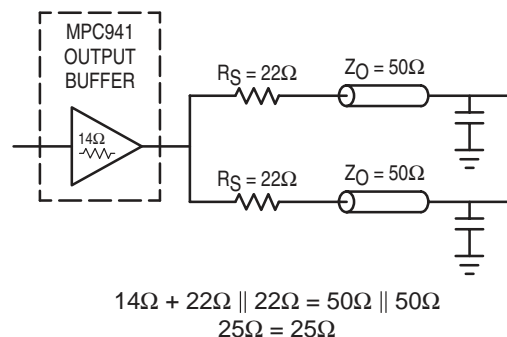

Figure 3. Optimized Dual Line Termination

Power Consumption of the MPC941 and Thermal Management

The MPC941 AC specification is guaranteed for the entire operating frequency range up to 250 MHz. The MPC941 power consumption and the associated long-term reliability may decrease the maximum frequency limit, depending on operating conditions such as clock frequency, supply voltage, output loading, ambient temperature, vertical convection and thermal conductivity of package and board. This section describes the impact of these parameters on the junction temperature and gives a guideline to estimate the MPC941 die junction temperature and the associated device reliability. For a complete analysis of power consumption as a function of operating conditions and associated long term device reliability please refer to the application note AN1545. According to the AN1545, the long-term device reliability is a function of the die junction temperature:

Table 7: Die junction temperature and MTBF

Junction temperature (°C)	MTBF (Years)
100	20.4
110	9.1
120	4.2
130	2.0

Increased power consumption will increase the die junction temperature and impact the device reliability (MTBF). According to the system-defined tolerable MTBF, the die junction temperature of the MPC941 needs to be controlled and the thermal impedance of the board/package should be optimized. The power dissipated in the MPC941 is represented in equation 1.

Where I_{CCQ} is the static current consumption of the MPC941, C_{PD} is the power dissipation capacitance per output, $(M)\Sigma C_L$ represents the external capacitive output load, N is the number of active outputs (N is always 27 in case of the MPC941). The MPC941 supports driving transmission lines to maintain high signal integrity and tight timing parameters. Any transmission line will hide the lumped capacitive load at the end of the board trace, therefore, ΣC_L is zero for controlled transmission line systems and can be eliminated from equation 1. Using parallel termination output termination results in equation 2 for power dissipation.

$$P_{TOT} = \left[I_{CCQ} + V_{CC} \cdot f_{CLOCK} \cdot \left(N \cdot C_{PD} + \sum_M C_L \right) \right] \cdot V_{CC} \quad \text{Equation 1}$$

$$P_{TOT} = V_{CC} \cdot \left[I_{CCQ} + V_{CC} \cdot f_{CLOCK} \cdot \left(N \cdot C_{PD} + \sum_M C_L \right) \right] + \sum_P [DC_Q \cdot I_{OH} \cdot (V_{CC} - V_{OH}) + (1 - DC_Q) \cdot I_{OL} \cdot V_{OL}] \quad \text{Equation 2}$$

$$T_J = T_A + P_{TOT} \cdot R_{thja} \quad \text{Equation 3}$$

$$f_{CLOCK,MAX} = \frac{1}{C_{PD} \cdot N \cdot V_{CC}^2} \cdot \left[\frac{T_{J,MAX} - T_A}{R_{thja}} - (I_{CCQ} \cdot V_{CC}) \right] \quad \text{Equation 4}$$

In equation 2, P stands for the number of outputs with a parallel or thevenin termination, V_{OL} , I_{OL} , V_{OH} and I_{OH} are a function of the output termination technique and DC_Q is the clock signal duty cycle. If transmission lines are used ΣC_L is zero in equation 2 and can be eliminated. In general, the use of controlled transmission line techniques eliminates the impact of the lumped capacitive loads at the end lines and greatly reduces the power dissipation of the device. Equation 3 describes the die junction temperature T_J as a function of the power consumption.

Where R_{thja} is the thermal impedance of the package (junction to ambient) and T_A is the ambient temperature. According to Table 7, the junction temperature can be used to estimate the long-term device reliability. Further, combining equation 1 and equation 2 results in a maximum operating frequency for the MPC941 in a series terminated transmission line system.

$T_{J,MAX}$ should be selected according to the MTBF system requirements and Table 7. R_{thja} can be derived from Table 8. The R_{thja} represent data based on 1S2P boards, using 2S2P boards will result in a lower thermal impedance than indicated below.

Table 8: Thermal package impedance of the 48ld LQFP

Convection, LFPM	R_{thja} (1P2S board), K/W
Still air	78
100 lfpm	68
200 lfpm	59
300 lfpm	56
400 lfpm	54
500 lfpm	53

If the calculated maximum frequency is below 250 MHz, it becomes the upper clock speed limit for the given application conditions. The following eight derating charts describe the safe frequency operation range for the MPC941. The charts were calculated for a maximum tolerable die junction temperature of 110°C (120°C), corresponding to a estimated MTBF of 9.1 years (4 years), a supply voltage of either 3.3V or 2.5V and series terminated transmission line or capacitive loading. Depending on a given set of these operating conditions and the available device convection a decision on the maximum operating frequency can be made.
