

Low voltage 8-bit constant current LED sink driver with output error detection for automotive applications

Datasheet - production data

Description

The STAP08DP05 is a monolithic, low voltage, low current power 8-bit shift register designed for LED panel displays. The STAP08DP05 contains an 8-bit serial-in, parallel-out shift register that feeds an 8-bit D-type storage register. In the output stage, eight regulated current sources are designed to provide 5-100 mA constant current to drive the LEDs.

The detection circuit checks 3 different conditions that can occur on the output line: short to GND, short to V_O or open line. The data detection results are loaded in the shift register and shifted out via the serial line output.

STAP08DP05 detection functionality is implemented without increasing the pin number. Through a secondary function of the output enable and latch pin (DM1 and DM2 respectively), a dedicated logic sequence allows the device to enter or leave detection mode. Through an external resistor, users can adjust the output current of the STAP08DP05, thus controlling the light intensity of the LEDs. In addition, the user can adjust the intensity of the brightness of the LEDs from 0% to 100% through the $\overline{OE}/DM2$ pin.

The STAP08DP05 guarantees a 20 V output driving capability, allowing users to connect more LEDs in series. The high clock frequency, 30 MHz, also satisfies the system requirement of high volume data transmission. The 3.3 V of voltage supply is very useful for applications that interface any microcontroller from 3.3 V. Compared with a standard TSSOP package, the TSSOP exposed pad increases the capability of heat dissipation by a factor of 2.5.

Features

- AECQ100 qualification
- Low voltage power supply down to 3 V
- 8 constant current output channels
- Adjustable output current through external resistor
- Short and open output error detection
- Serial data IN/parallel data OUT
- Able to drive 3.3 V microcontroller
- Output current: 5-100 mA
- 30 MHz clock frequency
- Available in high thermal efficiency TSSOP exposed pad
- ESD protection 2.5 kV HBM

Applications

- Dashboard and infotainment backlighting
- Exterior/interior lighting
- DTRLs

3 Maximum rating

Stressing the device above the rating listed in the “absolute maximum ratings” table may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the operating sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

10 Detection mode functionality

10.1 Phase one: “entering error detection mode“

From the “normal mode” condition the device can switch to “error detection mode” by a logic sequence on the $\overline{OE/DM2}$ and LE/DM1 pins as shown in the following table and diagram.

Table 12. Entering error detection mode truth table

CLK	1°	2°	3°	4°	5°
$\overline{OE/DM2}$	H	L	H	H	H
LE/DM1	L	L	L	H	L

Figure 17. Entering error detection mode timing diagram

After these five CLK cycles the device goes into the “error detection mode” and at the 6th rising edge of CLK, the SDI data are ready for sampling.

10.2 Phase two: “error detection mode“

The eight data bits must be set to “1” in order to set ON all the outputs during detection. The data are latched by LE/DM1 and after that the outputs are ready for the detection process. When the microcontroller switches OE/DM2 to LOW, the device drives the LEDs in order to analyze if an OPEN or SHORT condition has occurred.

Figure 18. Detection diagram

The status of the LEDs will be detected in 1 microsecond (minimum) and after this time the microcontroller sets OE/DM2 in HIGH state and the output data detection result will go to the microprocessor via SDO.

Detection mode and normal mode both use the same data format. As soon as all the detection data bits are available on the serial line, the device may go back to normal mode of operation. To re-detect the status, the device must go back in normal mode and re-enter error detection mode.

10.3 Phase three: “resuming normal mode”

The sequence for re-entering normal mode is shown in the following table and diagram.

Table 13. Resuming normal mode truth table

CLK	1°	2°	3°	4°	5°
$\overline{\text{OE}}/\text{DM2}$	H	L	H	H	H
$\text{LE}/\text{DM1}$	L	L	L	L	L

Figure 19. Resuming normal mode timing diagram

Note: For proper device operation the “entering error detection mode” sequence must be followed by a “resume mode” sequence, it is not possible to insert consecutive equal sequences.

10.4 Error detection conditions

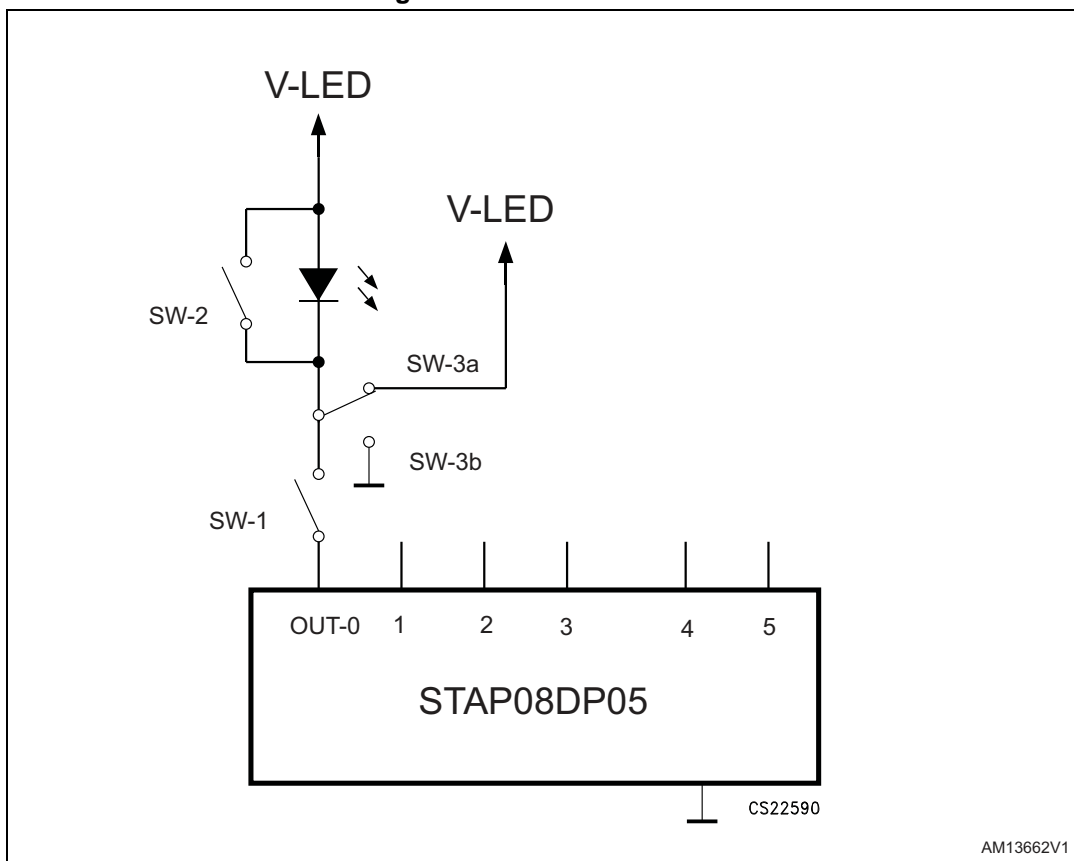

$V_{DD} = 3.3$ to 5 V temperature range 25 °C.

Table 14. Detection conditions

Configuration	Detect mode	Detection results		
SW-1 or SW-3b	Open line or output short to GND detected	$\implies I_{ODEC} \leq 0.5 \times I_O$	No error detected	$\implies I_{ODEC} \geq 0.5 \times I_O$
SW-2 or SW-3a	Short on LED or short to V-LED detected	$\implies V_O \geq 2.5V$	No error detected	$\implies V_O \leq 2.2 V$

Note: Where: I_O = the output current programmed by the R_{EXT} ; I_{ODEC} = the detected output current in detection mode.
