Functional Description

CY62167G is high-performance CMOS low-power (MoBL) SRAM devices with embedded ECC. This device is offered in dual chip-enable.

Devices with dual chip-enable are accessed by asserting both chip-enable inputs – \overline{CE}_1 as LOW and CE_2 as HIGH.

Data writes are performed by asserting the Write Enable input (\overline{WE}) LOW, and providing the data and address on device data (I/O_0 through I/O_{15}) and address (A_0 through A_{19}) pins respectively. The Byte High/Low Enable (\overline{BHE} , \overline{BLE}) inputs control byte writes, and write data on the corresponding I/O lines to the memory location specified. \overline{BHE} controls I/O_8 through I/O_{15} ; \overline{BLE} controls I/O_0 through I/O_7 .

Data reads are performed by asserting the Output Enable (\overline{OE}) input and providing the required address on the address lines. Read data is accessible on I/O lines (I/O_0 through I/O_{15}). Byte accesses can be performed by asserting the required byte enable signal (\overline{BHE} , \overline{BLE}) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O_0 through I/O_{15}) are placed in a HI-Z state when the device is deselected (\overline{CE}_1 HIGH / CE_2 LOW for dual chip-enable device), or control signals are de-asserted (\overline{OE} , \overline{BLE} , and \overline{BHE}).

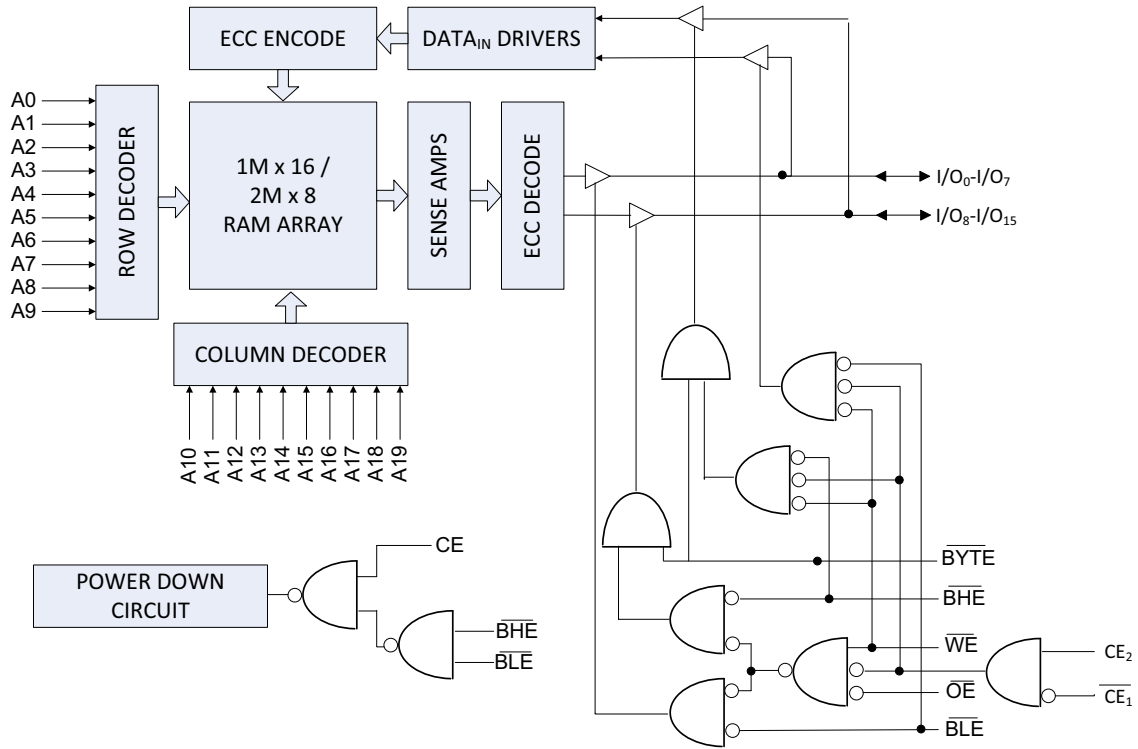

These devices also have a unique “Byte Power down” feature where if both the Byte Enables (\overline{BHE} and \overline{BLE}) are disabled, the devices seamlessly switches to standby mode irrespective of the state of the chip enable(s), thereby saving power.

The CY62167G device is available in a Pb-free 48-ball VFBGA and 48-pin TSOP I packages. The device in the 48-pin TSOP I package can also be configured to function as a 2M words × 8 bit device. The logic block diagram is on page 2. Refer to [Pin Configurations on page 4](#) and the associated footnotes for details.

Note

1. This device does not support automatic write-back on error detection.

Notes

- NC pins are not connected internally to the die and are typically used for address expansion to a higher-density device. Refer to the respective datasheets for pin configuration.
- The BYTE pin in the 48-pin TSOP I package must be tied to V_{CC} to use the device as a 1M × 16 SRAM. The 48-pin TSOP I package can also be used as a 2M × 8 SRAM by tying the BYTE signal to V_{SS}. In the 2M × 8 configuration, pin 45 is A20, while BHE, BLE and I/O₈ to I/O₁₄ pins are not used.
- Indicates the value for the center of Distribution at 3.0 V, 25 °C and not 100% tested.

Notes

14. Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for $V_{CC} \geq 3$ V) and $V_{CC}/2$ (for $V_{CC} < 3$ V), and input pulse levels of 0 to 3 V (for $V_{CC} \geq 3$ V) and 0 to V_{CC} (for $V_{CC} < 3$ V). Test conditions for the read cycle use output loading shown in AC Test Loads and Waveforms section, unless specified otherwise.

15. At any temperature and voltage condition, t_{HZOE} is less than t_{LZCE} , t_{HZBE} is less than t_{LZBE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any device.

16. t_{HZOE} , t_{HZCE} , t_{HZBE} , and t_{HZWE} transitions are measured when the outputs enter a high impedance state.

17. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write. Any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.

- 19. \overline{WE} is HIGH for read cycle.
- 20. For all dual chip enable devices, \overline{CE} is the logical combination of \overline{CE}_1 and CE_2 . When \overline{CE}_1 is LOW and CE_2 is HIGH, \overline{CE} is LOW; when \overline{CE}_1 is HIGH or CE_2 is LOW, \overline{CE} is HIGH.
- 21. Address valid prior to or coincident with \overline{CE} LOW transition.

Notes

- 22. For all dual chip enable devices, \overline{CE} is the logical combination of \overline{CE}_1 and CE_2 . When \overline{CE}_1 is LOW and CE_2 is HIGH, \overline{CE} is LOW; when \overline{CE}_1 is HIGH or CE_2 is LOW, \overline{CE} is HIGH.
- 23. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. The data input setup and hold timing must refer to the edge of the signal that terminates the write.
- 24. Data I/O is in HI-Z state if $\overline{CE} = V_{IH}$, or $\overline{OE} = V_{IH}$ or \overline{BHE} , and/or $\overline{BLE} = V_{IH}$.

- 25. For all dual chip enable devices, \overline{CE} is the logical combination of \overline{CE}_1 and CE_2 . When \overline{CE}_1 is LOW and CE_2 is HIGH, \overline{CE} is LOW; when \overline{CE}_1 is HIGH or CE_2 is LOW, \overline{CE} is HIGH.
- 26. The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE}_1 = V_{IL}$, \overline{BHE} or \overline{BLE} or both = V_{IL} , and $CE_2 = V_{IH}$.
