LMH1251

Y_PB_PR to RGBHV Converter and 2:1 Video Switch

General Description

The LMH1251 is a wideband 2:1 analog video switch with an integrated Y_PB_PR to RGBHV converter. The device accepts one set of Y_PB_PR inputs and one set of RGB/HSYNC/VSYNC inputs. Based on the input selected, the output will be either a decoded TV or buffered PC video signal.

The LMH1251 has a SYNC separator and processor that is capable of extracting sync timing information from both Standard Definition Television (SDTV) and High Definition Television (HDTV) inputs. It provides bi-level sync, and tri-level sync separation.

The color space conversion from Y_PB_PR to RGB in the LMH1251 is realized with a very high precision fully analog dematrixer which provides superior chroma accuracy that is less than 2.5% of amplitude and 1.5° of phase error on a vectorscope. It is equipped with a smart video detection circuit which automatically senses SDTV and HDTV video formats and applies the appropriate color space conversion.

The LMH1251 is capable of handling SDTV, HDTV, XGA, SXGA, and UXGA video formats, which makes it an ideal solution for enhancing value in applications ranging from LCD monitors, to set-top boxes, to projectors. The LMH1251 is part of the LMH® high speed amplifier family, and is offered in a TSSOP-24 package.

Features

- Y_PB_PR to RGBHV conversion
- Y_PB_PR path: 70 MHz, -3 dB, 700 mV_{PP} bandwidth
- RGB path: 400 MHz, -3 dB, 700 mV_{PP} bandwidth
- Supports PC video display resolutions up to UXGA (1600 x 1200 @ 75 Hz)
- Supports 480i, 480p, 576i, 576p, 720p, 1080i, and 1080p
- Smart video format detection for SD and HD
- Power save mode

Applications

- TFT LCD monitor
- CRT monitor
- Set-top box
- Display projector

Connection Diagram

Truth Table

TABLE 1. Input Select

Pin 24	OUT
0	RGBHV input Ch
1	Y _B P _R input Ch

TABLE 2. Format/Conversion Select

Pin 23	Pin 22	SYNC	Format Detection	Conversion Scheme
0	0	Bi-Level	Manual	480i/480p
0	1	Tri-Level	Manual	720p/1080i
1	*Outputs 0	Bi-Level	Auto	480i/480p
1	*Outputs 1	Tri-Level	Auto	720p/1080i

* When Pin 23 is set high, the LMH1251 is in Auto Mode, in which it can detect the incoming video format (SD or HD) and apply the appropriate color conversion and sync processing. With Auto Mode, Pin 22 becomes an output pin, and will either output a logic high or low to notify the user of the format that is being detected by the LMH1251. If Pin 23 is set low, the LMH1251 is in Manual Mode, in which the user must specify the format with Pin 22. With Manual Mode, Pin 22 is an input pin. Since Pin 22 is a bi-directional pin, care must be given not to apply any voltages to it when it is in the Auto Mode, in which it functions as an output pin. The use of the Auto Mode with Pin 22 left floating is typically recommended.

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is intended to be functional, but specific performance is not guaranteed. For guaranteed specifications, see the Electrical Characteristics tables.

Note 2: Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. All video inputs must be properly terminated.

Note 3: All voltages are measured with respect to GND, unless otherwise specified.

Note 4: Human Body Model, applicable std. MIL-STD-883, Method 3015.7. Machine Model, applicable std. JESD22-A115-A (ESD MM std. of JEDEC). Field-Induced Charge-Device Model, applicable std. JESD22-C101-C (ESD FICDM std. of JEDEC).

Note 5: The maximum power dissipation is a function of $T_{J(MAX)}$, θ_{JA} . The maximum allowable power dissipation at any ambient temperature is $P_D = (T_{J(MAX)} - T_A) / \theta_{JA}$. All numbers apply for packages soldered directly onto a PC Board.

Note 6: Input from RGB signal generator: $t_r, t_f = 1.5 \text{ ns}$. Input from SDTV $Y_P P_R$ signal generator: $t_r, t_f = 15 \text{ ns}$. Input from HDTV $Y_P P_R$ signal generator: $t_r, t_f = 8 \text{ ns}$.

Note 7: Typical values represent the most likely parametric norm as determined at the time of characterization. Actual typical values may vary over time and will also depend on the application and configuration. The typical values are not tested and are not guaranteed on shipped production material.

Note 8: Datasheet min/max specification limits are guaranteed by design, test, or statistical analysis. The guaranteed specifications apply only for the test conditions listed. Some performance characteristics may change when the device is not operated under the listed test conditions.

Note 9: The supply current specified is the quiescent current for V_{CC} and 5V with $R_L = \infty$. Load resistors are not required and are not used in the test circuit; therefore, all the supply current is used by the device.

Note 10: Linearity Error is the maximum variation in step height of a 16 step staircase input signal waveform with a $0.7 V_{PP}$ level at the input. All 16 are steps equal, with each at least 100 ns in duration.

Note 11: ΔA_V track is a measure of the ability of any two amplifiers to track each other and quantifies the matching of the three gain stages. It is the difference in gain change between any two amplifiers with the contrast set to $A_V C-50\%$ and measured relative to the A_V max condition. For example, at A_V max the three amplifiers' gains might be 12.1 dB, 11.9 dB, and 11.8 dB and change to 2.2 dB, 1.9 dB and 1.7 dB respectively for contrast set to $A_V C-50\%$. This yields a typical gain change of 10.0 dB with a tracking change of $\pm 0.2 \text{ dB}$.

Note 12: The Machine Model ESD test is covered by specification EIAJ IC-121-1981. A 200 pF cap is charged to the specific voltage, then discharged directly into the IC with no external series resistor (resistance of discharge path must be under 50Ω).

Note 13: Measure output levels of the other two undriven amplifiers relative to the driven amplifier to determine channel separation. Terminate the undriven amplifier inputs to simulate generator loading. Repeat test at $f_{IN} = 10 \text{ MHz}$ for $V_{SEP} 10 \text{ MHz}$.

Note 14: Any three color bar signals can be used as test signals. The RGB outputs shall be used to calculate the amplitudes and phases of the chroma results. These should fall within the limits specified.

Typical Performance Characteristics Unless otherwise noted: $T_A = 25^\circ\text{C}$, $V_{CC} = +5.0\text{V}$, $\text{RGB Video}_{IN} = 0.7 V_{PP}$, $\text{Y Video}_{IN} = 0.7 V_{PP}$, $\text{P}_B\text{P}_R \text{ Video}_{IN} = \pm 350 \text{ mV}$, $C_L = 8 \text{ pF}$, $\text{Video Outputs} = 0.7 V_{PP}$.

Application Information

GENERAL INFORMATION

The LMH1251 is a high speed triple 2:1 video multiplexer with an integrated sync processor and color space converter. One input channel accepts standard RGBHV PC graphics video and the second input channel accepts $Y_{P_B}P_R$ component video. If the first input of the MUX is selected, the device will output the RGBHV video from the input with unity gain. If the second input of the MUX is selected, sync processing and color space conversion will be performed on the $Y_{P_B}P_R$ component signals to provide an equivalent RGBHV signal at the output.

$Y_{P_B}P_R$ to RGBHV PROCESSING

The LMH1251 is capable of processing 480i, 480p, 576i, 576p, 720p, 1080i, and 1080p $Y_{P_B}P_R$ component video signals only. S-Video, composite NTSC, or composite PAL video will not be converted by the LMH1251. For High Definition, 720p and 1080i/1080p video, the LMH1251 will convert the luma and chroma signals into primary RGB signals according to the linear arithmetic formula specified in the EIA/CEA-770.3-C Standard for High Definition Analog Component TV. For Standard Definition video, the LMH1251 will perform the conversion according to the linear arithmetic formula specified in the EIA/CEA-770.2-C Standard for Standard Definition Analog Component TV. The advanced analog architecture that is employed to perform the color space conversion is precise to within 2.5% of amplitude and 1.5° of phase error on a vectorscope with a color bar test signal. This is illustrated with a vectorscope plot of a converted color bar signal in the 720p format show in the Typical Performance Characteristics section.

Note that although 480i/576i component video is supported by the LMH1251, most PC display monitors cannot handle such line rates. Typically, only 480p, 576p, 720p, and 1080i/1080p are within the displayable line rate range of LCD and CRT monitors. Furthermore, the scaler in LCD monitor systems must include a de-interlacer for it to display interlaced video such as with 1080i.

Component Video Formats Supported By The LMH1251

- 480i*
- 480p
- 576i*
- 576p
- 720p
- 1080i at 25, 29.97, and 30 Hz frame rate
- 1080p at 25, 29.97, and 30 Hz frame rate

Note: *These formats with Macrovision are not supported. See Macrovision Compatibility section for more information.

AUTO/MANUAL FORMAT DETECTION

The LMH1251 can either automatically detect the input format of the component video source, or it can be put in a manual mode where the MCU has the flexibility to specify which $Y_{P_B}P_R$ to RGBHV processing scheme for the device to apply depending on the input format. If a logic high is applied to Pin 23, the LMH1251 will be in the AUTO detection mode, which is typically recommended. In this mode, the device will appropriately use the proper $Y_{P_B}P_R$ to RGB processing scheme based on its input format detection. If a logic low is applied to Pin 23, the LMH1251 will be in the manual detection mode. In this mode, the MCU must apply a logic low to Pin 22 if the processing scheme is for SDTV video formats, and a logic high if the processing scheme is for HDTV formats.

Note that in the AUTO mode, Pin 22 becomes an output pin, and outputs a logic low if an SD video input is detected and a logic high if an HD video input is detected, as notification to the MCU.

MACROVISION COMPATIBILITY

The LMH1251 is compatible with the Macrovision Video Copy Protection System commonly used in 480p/576p progressive-scan DVD video sources. The LMH1251 does not support 480i/576i formats with Macrovision enabled. Macrovision, which is enabled by special circuitry inside many DVD players, embeds pseudo sync pulses and pseudo video pulses into the source signal during the vertical blanking interval. This system is intended to prohibit and deter analog video recording.

For 480p/576p formats with Macrovision enabled, the internal sync processor of the LMH1251 will output the true H sync pulses only and effectively ignore the pseudo sync pulses; its video processor will apply proper SDTV color space conversion, and the pseudo video pulses will pass through to comply with Macrovision.

POWER SAVE MODE

The LMH1251 is equipped with a power saving mode which is controlled by Pin 21. This pin is a logic level input. The device will enter a low power mode when the power save pin is applied with a logic high by the MCU. Under these conditions, the IC reduces its current consumption to a minimum as specified in the Electrical Characteristics section. However, the sync processor and switch will always remain active. During power save mode, the RGB video outputs are held to the blank level, while the sync signals are allowed to continue to be processed and/or passed through. Based on the absence or presence of sync signals at the output of the LMH1251, the MCU can determine whether to bring the system to a low power consumption state.

INTERNAL VOLTAGE REFERENCE

Proper operation of the LMH1251 requires a very accurate reference voltage. This voltage is generated in the V_{REF} block. The output of the V_{REF} stage goes to a number of blocks in the video sections and sets the internal bias. To insure an accurate voltage over temperature, an external resistor is used to set the current in the V_{REF} stage. The external resistor is connected to Pin 15. This resistor should be 1% and have a temperature coefficient under 100 ppm/°C.

H SYNC AND V SYNC CHARACTERISTICS

When the RGBHV input is selected, the LMH1251 will produce H and V sync output signals of the same sync polarities as the H and V sync input signals. For example, VESA standard timing input signals with positive, leading edge sync pulses will produce positive, leading edge pulses in the H and V sync output signals. However when the $Y_{P_B}P_R$ input is selected, both sync outputs are always positive, leading edge syncs, set by the internal sync processor.

Display systems typically sync lock to negative edges of H and V sync signals, and some displays may have polarity correction to accommodate either positive or negative edges. Logic inverters can be used to invert the H and V sync output signals of the LMH1251 to satisfy the negative edge requirement.

It is worth noting that when $Y_{P_B}P_R$ is selected with an SDTV input format, some H sync output pulses will be half the width of the normal H sync pulses due to the narrow equalization pulses in the vertical blanking interval. When the H sync signal changes from full to half width pulses, or vice versa, the H

sync period or scan rate changes with respect to the negative sync edges. These brief changes in the H sync period may cause a negative-edge triggered horizontal PLL to lose sync lock momentarily, which can cause the on-screen picture to distort or blank repeatedly. This condition can be rectified using a logic inverter to produce negative, leading edge H sync pulses. When the inverted H sync signal changes from full to half width pulses, or vice versa, the H sync period will remain constant with respect to the negative edges, which is correct H sync operation for negative-edge triggered displays.

OUTPUT DRIVE CHARACTERISTICS

The LMH1251 is designed to interface with an ADC or preamplifier through an AC coupling capacitor as shown below in Figure 1. The RGB outputs of the LMH1251 are 700 mV_{PP} video signals with the black level at approximately 2.1V (typ), which is the chip's internal voltage reference level. The H sync and V sync output signals are CMOS logic outputs that swing rail-to-rail.

The RGBHV outputs cannot be used to drive standard 150Ω video loads and require high-bandwidth buffers for this kind of application. For example, if the LMH1251 is to be designed into a stand-alone converter box application, the configuration in Figure 2 is recommended. To drive a display monitor over a standard VGA cable, a wideband, low distortion triple video buffer, such as the LMH6739, can be used with a gain of +2 to drive the RGB video signals of the LMH1251, and logic inverters can be used to drive its H and V sync signals.

20151908

FIGURE 1. Typical LMH1251 Application

20151907

FIGURE 2. Simplified Application Diagram for Driving a VGA Cable

LAYOUT CONSIDERATIONS

The most important point to note regarding the layout of the LMH1251 on a PCB is that the trace length between the output pins of the LMH1251 and the input AC coupling capacitors of the next stage ADC or preamplifier must be as minimal as possible. The trace lengths of the H Sync and V Sync outputs should also be minimized, as the capacitive loading on these outputs must not exceed 6 pF. For long signal paths leading up to the input of the LMH1251, controlled impedance lines

should be used, along with impedance matching elements. Bypass capacitors should be placed as close as possible to the supply pins of the device. The larger electrolytic bypass capacitor can be located farther from the device. The 10 kΩ external resistor should also be placed as close as possible to the R_{EXT} pin. All video signals must be kept away from the R_{EXT} pin (15). This pin has a very high input impedance and will pick up any high frequency signals routed near it.
