LOW-NOISE, HIGH-SPEED, PRECISION OPERATIONAL AMPLIFIERS

D3176, FEBRUARY 1989

- Direct Replacements for PMI and LTC OP-27 and OP-37 Series

Features of OP-27A, OP-27C, OP-37A, and OP-37C:

- Maximum Equivalent Input Noise Voltage:
3.8 nV/√Hz at 1 kHz
5.5 nV/√Hz at 10 Hz
- Very Low Peak-to-Peak Noise Voltage at 0.1 Hz to 10 Hz . . . 80 nV Typ
- Low Input Offset Voltage . . . 25 μV Max
- High Voltage Amplification . . . 1 V/μV Min

Feature of OP-37 Series:

- Minimum Slew Rate . . . 11 V/μs

description

The OP-27 and OP-37 operational amplifiers combine outstanding noise performance with excellent precision and high-speed specifications. The wideband noise is only 3 nV/√Hz, and with the 1/f noise corner at 2.7 Hz, low noise is maintained for all low-frequency applications.

The outstanding characteristics of the OP-27 and OP-37 make these devices excellent choices for low-noise amplifier applications requiring precision performance and reliability. Additionally, the OP-37 is free of latch-up in high-gain, large-capacitive-feedback configurations.

The OP-27 series is compensated for unity gain. The OP-37 series is decompensated for increased bandwidth and slew rate and is stable down to a gain of 5.

The OP-27A, OP-27C, OP-37A, and OP-37C are characterized for operation over the full military temperature range of -55°C to 125°C. The OP-27E, OP-27G, OP-37E, and OP-37G are characterized for operation from -25°C to 85°C.

absolute maximum ratings over operating free-air temperature range (unless otherwise noted)

Supply voltage, VCC+ (see Note 1)	22 V
Supply voltage, VCC- (see Note 1)	-22 V
Input voltage	VCC±
Duration of output short circuit	unlimited
Differential input current (see Note 2)	±25 mA
Continuous power dissipation	see Dissipation Rating Table
Operating free-air temperature range: OP-27A, OP-27C, OP-37A, OP-37C	-55°C to 125°C
OP-27E, OP-27G, OP-37E, OP-37G	-25°C to 85°C
Storage temperature range	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds: JG or L package	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds: P package	260°C

- NOTES: 1. All voltage values are with respect to the midpoint between VCC+ and VCC- unless otherwise noted.
2. The inputs are protected by back-to-back diodes. Current-limiting resistors are not used in order to achieve low noise. Excessive input current will flow if a differential input voltage in excess of approximately ±0.7 V is applied between the inputs unless some limiting resistance is used.

TYPICAL APPLICATION DATA

general

The OP-27 and OP-37 series devices may be inserted directly into OP-07, OP-05, μ A725, and SE5534 sockets with or without removing external compensation or nulling components. In addition, the OP-27 and OP-37 may be fitted to μ A741 sockets by removing or modifying external nulling components.

noise testing

Figure 34 shows a test circuit for 0.1-Hz to 10-Hz peak-to-peak noise measurement of the OP-27 and OP-37. The frequency response of this noise tester indicates that the 0.1-Hz corner is defined by only one zero. Because the time limit acts as an additional zero to eliminate noise contributions from the frequency band below 0.1 Hz, the test time to measure 0.1-Hz to 10-Hz noise should not exceed 10 seconds.

TYPICAL APPLICATION DATA

T-79-06-10

When measuring noise on a large number of units, a noise-voltage density test is recommended. A 10-Hz noise-voltage density measurement correlates well with a 0.1-Hz to 10-Hz peak-to-peak noise reading since both results are determined by the white noise and the location of the 1/f corner frequency.

Figure 35 shows a circuit measuring current noise and the formula for calculating current noise.

FIGURE 35. CURRENT NOISE TEST CIRCUIT AND FORMULA

offset voltage adjustment

The input offset voltage and temperature coefficient of the OP-27 and OP-37 are permanently trimmed to a low level at wafer testing. However, if further adjustment of V_{IO} is necessary, using a 10-k Ω nulling potentiometer, as shown in Figure 36, does not degrade the temperature coefficient $\propto V_{IO}$. Trimming to a value other than zero creates an $\propto V_{IO}$ of $V_{IO}/300 \mu\text{V}/^\circ\text{C}$. For example, if V_{IO} is adjusted to 300 μV , the change in $\propto V_{IO}$ is 1 $\mu\text{V}/^\circ\text{C}$.

The adjustment range with a 10-k Ω potentiometer is approximately $\pm 2.5 \text{ mV}$. If a smaller adjustment range is needed, the sensitivity and resolution of the nulling can be improved by using a smaller potentiometer in conjunction with fixed resistors. The example in Figure 37 has an approximate null range of $\pm 200 \mu\text{V}$.

FIGURE 37. INPUT OFFSET VOLTAGE ADJUSTMENT WITH IMPROVED SENSITIVITY

offset voltage and drift

Unless proper care is exercised, thermocouple effects caused by temperature gradients across dissimilar metals at the contacts to the input terminals can exceed the inherent temperature coefficient $\propto V_{IO}$ of the amplifier. Air currents should be minimized, package leads should be short, and the two input leads should be close together and at the same temperature.

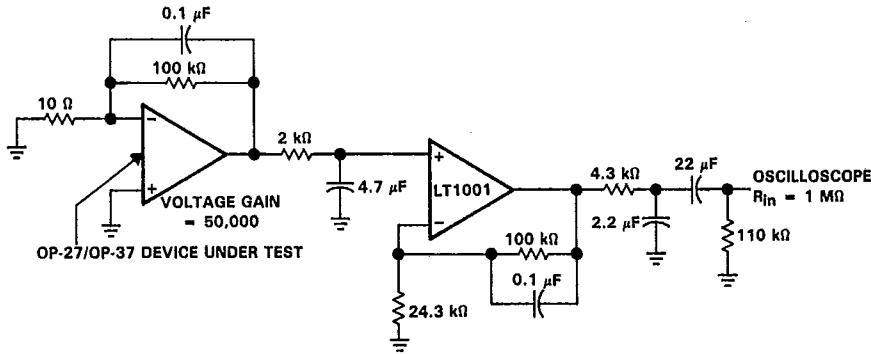

The circuit shown in Figure 38 measures offset voltage. This circuit can also be used as the burn-in configuration for the OP-27 and OP-37, with the supply voltage increased to $\pm 20 \text{ V}$, $R_1 = R_3 = 10 \text{ k}\Omega$, $R_2 = 200 \Omega$, and $A_{VP} = 100$.

Operational Amplifiers

NOTE: All capacitor values are for non-polarized capacitors only.

FIGURE 34. 0.1-Hz TO 10-Hz PEAK-TO-PEAK NOISE TEST CIRCUIT AND FREQUENCY RESPONSE

Measuring the typical 80-nV peak-to-peak noise performance of the OP-27 and OP-37 requires the following special test precautions:

1. The device should be warmed up for at least five minutes. As the operational amplifier warms up, the offset voltage typically changes $4 \mu\text{V}$ due to the chip temperature increasing from 10°C to 20°C starting from the moment the power supplies are turned on. In the 10-s measurement interval, these temperature-induced effects can easily exceed tens of nanovolts.
2. For similar reasons, the device should be well shielded from air currents to eliminate the possibility of thermoelectric effects in excess of a few nanovolts, which would invalidate the measurements.
3. Sudden motion in the vicinity of the device should be avoided, as it produces a feedthrough effect that increases observed noise.

TYPICAL APPLICATION DATA

NOTE: Resistors must have low thermoelectric potential.

unity gain buffer applications

The resulting output waveform when $R_f \leq 100 \Omega$ and the input is driven with a fast large-signal pulse ($> 1 \text{ V}$) is shown in the pulsed-operation diagram in Figure 39.

FIGURE 39. PULSED OPERATION

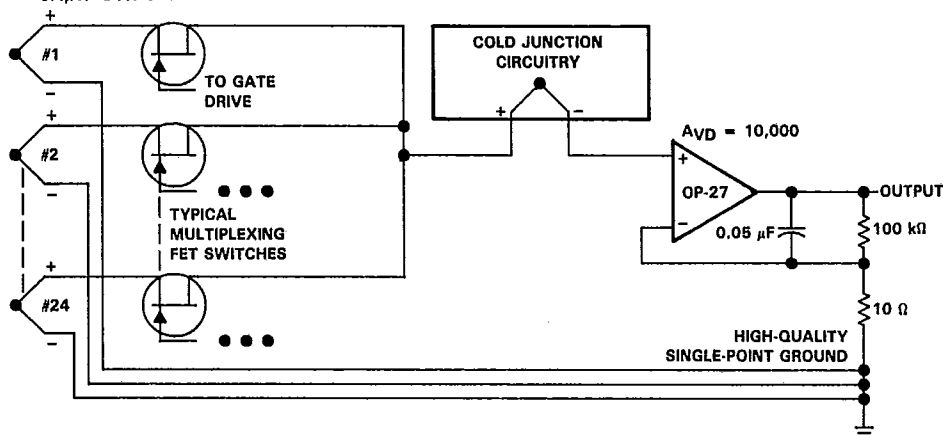

During the initial (fast-feedthrough-like) portion of the output waveform, the input protection diodes effectively short the output to the input, and a current, limited only by the output short-circuit protection, is drawn by the signal generator. When $R_f \geq 500 \Omega$, the output is capable of handling the current requirements (load current $\leq 20 \text{ mA}$ at 10 V), the amplifier stays in its active mode, and a smooth transition occurs. When $R_f > 2 \text{ k}\Omega$, a pole is created with R_f and the amplifier's input capacitance, creating additional phase shift and reducing the phase margin. A small capacitor (20 pF to 50 pF) in parallel with R_f eliminates this problem.

TYPICAL APPLICATION

T-79-06-10

TYPE S THERMOCOUPLES
 5.4 $\mu\text{V}/^\circ\text{C}$ AT 0 $^\circ\text{C}$

NOTE A: If 24 channels are multiplexed per second, and the output is required to settle to 0.1% accuracy, the amplifier's bandwidth cannot be limited to less than 30 Hz. The peak-to-peak noise contribution of the OP-27 will still be only 0.11 μV , which is equivalent to an error of only 0.02 $^\circ\text{C}$.
